P6.1 [5 points]
For a one-dimensional system with the Hamiltonian

$$
\begin{equation*}
H=\frac{p^{2}}{2}-\frac{1}{2 q^{2}}, \tag{1}
\end{equation*}
$$

show that there is a constant of the motion

$$
\begin{equation*}
D=\frac{p q}{2}-H t \tag{2}
\end{equation*}
$$

$\underline{\text { P6.2 }}[5+3+3=11$ points $]$
Consider a particle of mass $m$ moving in two dimensions in a potential well. Let us choose the origin of our coordinate system at the minimum of this well. The well would be termed isotropic if the potential did not depend on the polar angle.
(a) First, consider the anisotropic potential in a given Cartesian coordinate system:

$$
\begin{equation*}
V\left(x_{1}, x_{2}\right)=\frac{k}{2}\left(x_{1}^{2}+x_{2}^{2}\right)+k^{\prime} x_{1} x_{2} ; \quad k>k^{\prime}>0 \tag{3}
\end{equation*}
$$

Find the eigenfrequencies and normal modes, preferably by reasoning rather than brute-force matrix diagonalization. Give a physical interpretation of the normal modes.
(b) Use a qualitative physics-based argument to write down two independent constants of the motion. Verify your choice using the Poisson bracket equation

$$
\begin{equation*}
\dot{u}=\{u, H\}_{\mathrm{PB}}+\frac{\partial u}{\partial t} \tag{4}
\end{equation*}
$$

where $u=u(q, p, t)$ and $H$ is the Hamiltonian.
(c) The oscillator becomes isotropic if $k^{\prime}=0$. Again use a qualitative physics-based argument to write down an additional independent constant of motion if $k^{\prime}=0$, and verify your choice with the PB equation above.

## P6.3 [8 points]

Verify the Poisson bracket equation

$$
\begin{equation*}
\left\{L_{i}, L_{j}\right\}=\epsilon_{i j k} L_{k} \tag{5}
\end{equation*}
$$

among the Cartesian components of angular momentum of a spherical pendulum (i.e. with two angular degrees of freedom) of mass $m$ in a gravitaional field of acceleration $\vec{g}$ pointing opposite to the pole. $\epsilon_{i j k}$ represents
the Levi-Civita tensor ${ }^{1}$.
Hint: Start with expressing the Lagrangian in spherical coordinates: $\mathcal{L}=$ $\mathcal{L}(\theta, \phi, \dot{\theta}, \dot{\phi})$.

P6.4 $[2+5+2+2=11$ points]
Consider a system with a time-dependent Hamiltonian

$$
\begin{equation*}
H(q, p, t)=H_{0}(q, p)-\epsilon q \sin (\omega t) \tag{6}
\end{equation*}
$$

where $\epsilon$ and $\omega$ are known constants and $\frac{\partial H_{0}}{\partial t}=0$.
(a) Derive Hamilton's canonical equations of motion for the system.
(b) Use a canonical transformation generating function $G(q, P, t)$ to find a new Hamiltonian $H^{\prime}$ and new canonical variables $Q, P$ such that $H^{\prime}(Q, P)=H_{0}(q, p)$.
Hint: The partial differential equations do not tell us how $q$ and $P$ are related in the generating function. We can take an educated guess though. $G=q P-\frac{\epsilon q}{\omega} \cos (\omega t)$ works.
(c) Verify that Hamilton's canonical equations of motion are invariant under the transformation.
(d) Suggest a possible physical interpretation of the time-dependent term in $H$.

P6.5 $[2+3=5$ points $]$
The Hamiltonian $H=\frac{p^{2}}{2 m}+\frac{m \omega^{2} q^{2}}{2}$ describes a simple harmonic oscillator of mass $m$ and frequency $\omega$. Introducing the transformation

$$
\begin{equation*}
x_{1} \equiv \omega \sqrt{m} q, \quad x_{2} \equiv \frac{p}{\sqrt{m}}, \quad \tau \equiv \omega t \tag{7}
\end{equation*}
$$

we obtain $H=\frac{1}{2}\left(x_{1}^{2}+x_{2}^{2}\right)$.
(a) What is the generating function $\hat{\Phi}_{1}\left(x_{1}, y_{1}\right)$ for the canonical transformation $\left\{x_{1}, x_{2}\right\} \rightarrow\left\{y_{1}, y_{2}\right\}$ that corresponds to the function $\Phi(q, Q)=$ $\frac{m \omega q^{2}}{2} \cot Q ?$
(b) Calculate the matrix $M_{i j} \equiv \frac{\partial x_{i}}{\partial y_{j}}$ and confirm that $\operatorname{det} \mathbf{M}=1$ and $\mathbf{M}^{T} \epsilon \mathbf{M}=\epsilon(\epsilon$ is the antisymmetric matrix used in the lectures to put the coordinates $q_{i}$ and momenta $p_{i}$ in a single array $w_{\mu}$ ).

Hint: $y_{1}=Q, y_{2}=\omega P$, where $Q$ and $P$ are the new generalized coordinates and momenta, respectively.

[^0]
[^0]:    ${ }^{1}$ In 3 dimensions, the (antisymmetric) Levi-Civita tensor is defined as $\epsilon_{123}=\epsilon_{231}=$ $\epsilon_{312}=1, \epsilon_{132}=\epsilon_{213}=\epsilon_{321}=-1$, all other $\epsilon_{i j k}=0$. In $n$ dimensions $\epsilon_{123 \ldots n}$ and its even permutations (i.e., even number of swapping of adjacent indices) are 1 , odd permutations -1 , all others 0.
