UNIVERSITY

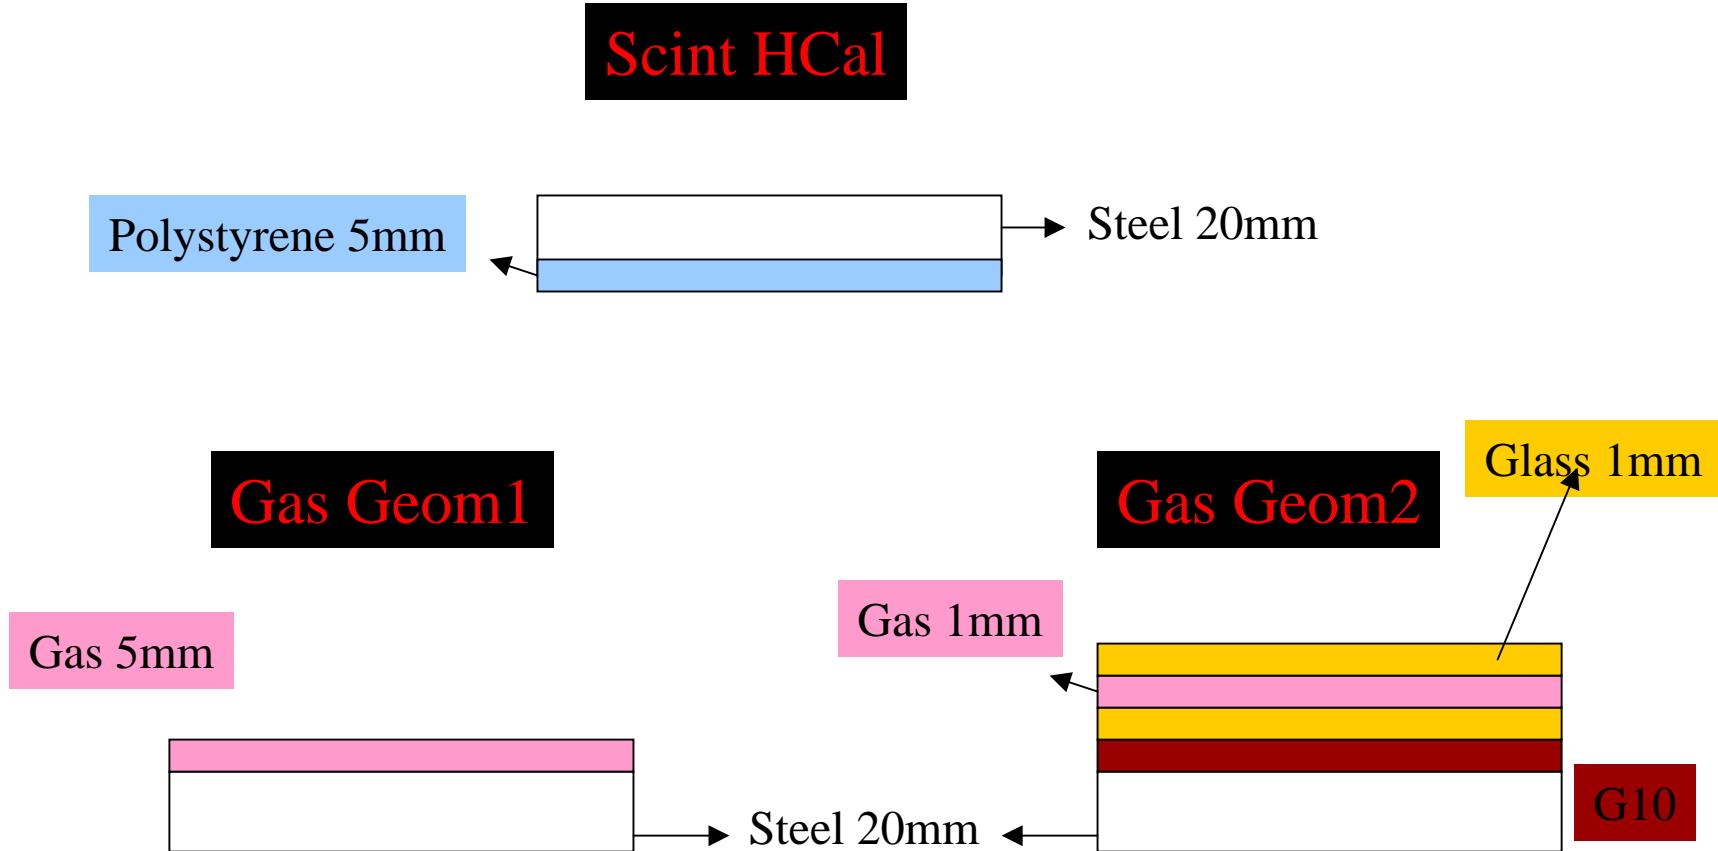

International Linear Collider
Large Detector Meeting
LLR, Paris, January 13–15, 2005

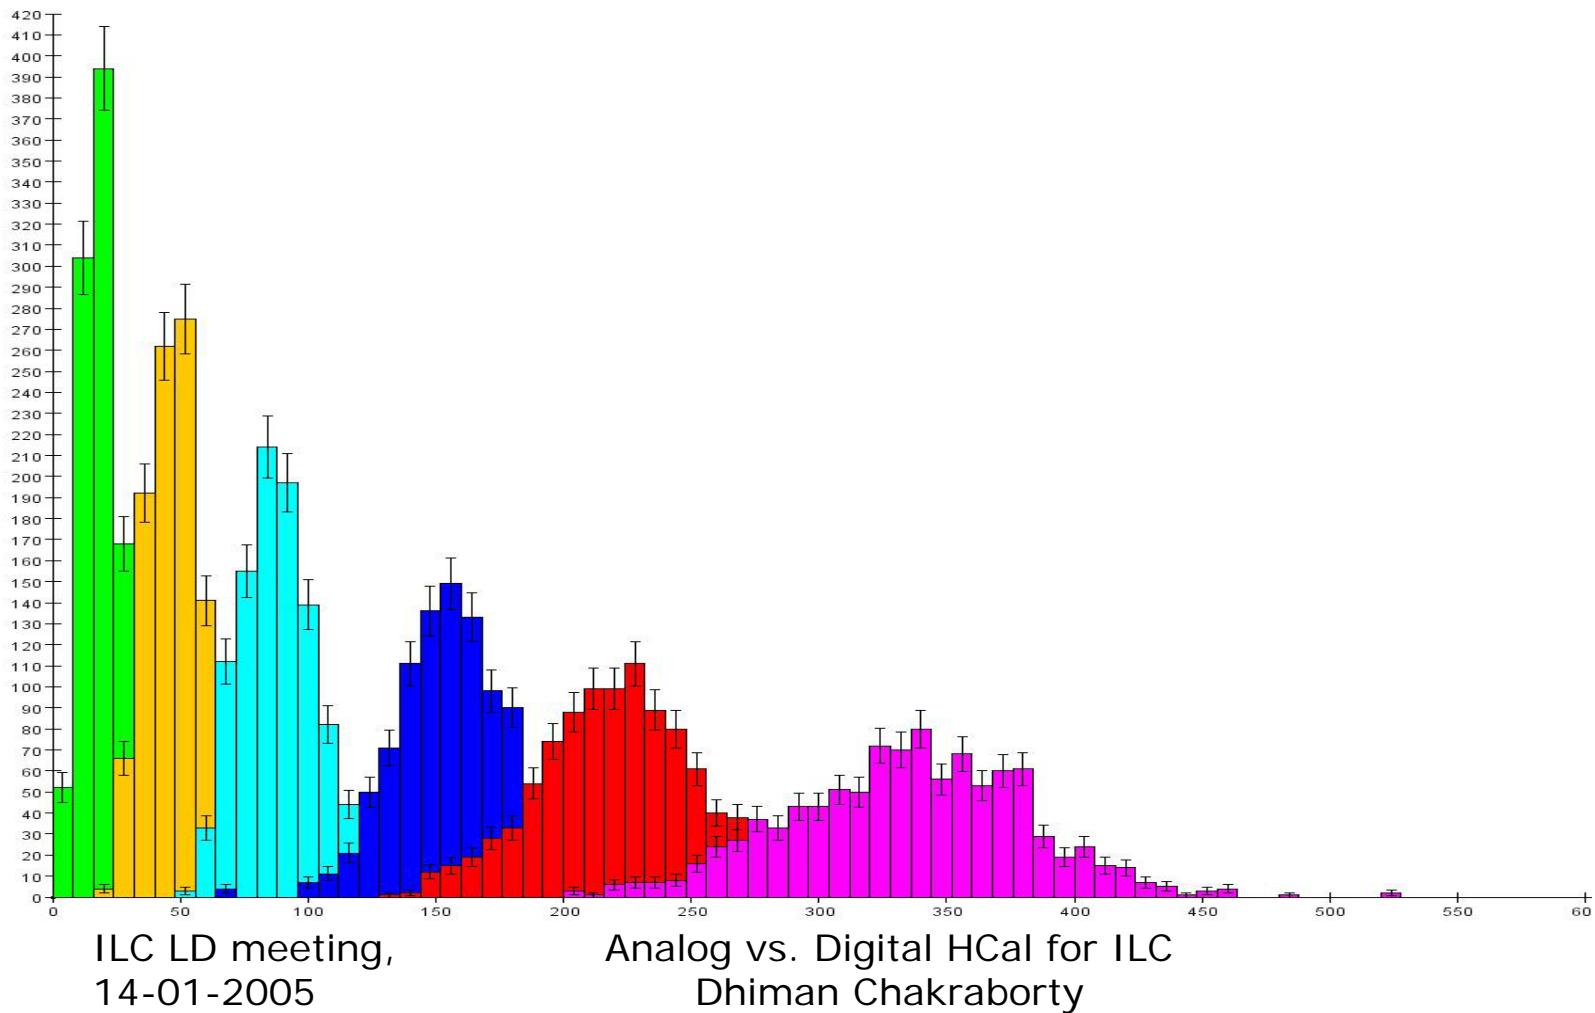

Introduction

- We consider a hadronic calorimeter with a few thresholds (1–3).
- Compare gas and scintillator as live media:
 - Single particle energy resolution,
 - Shower width,
 - Clustering.

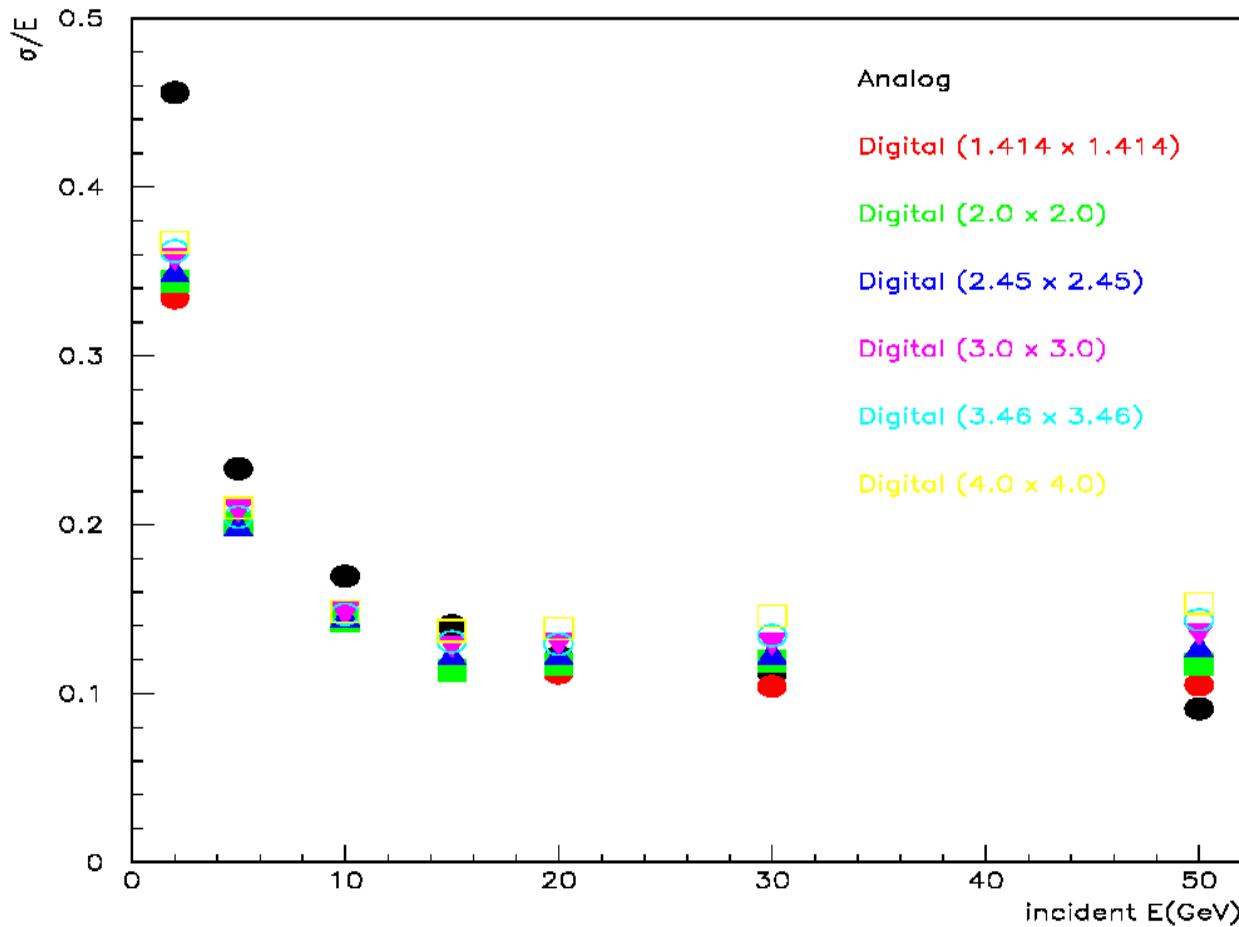

Geometries Considered

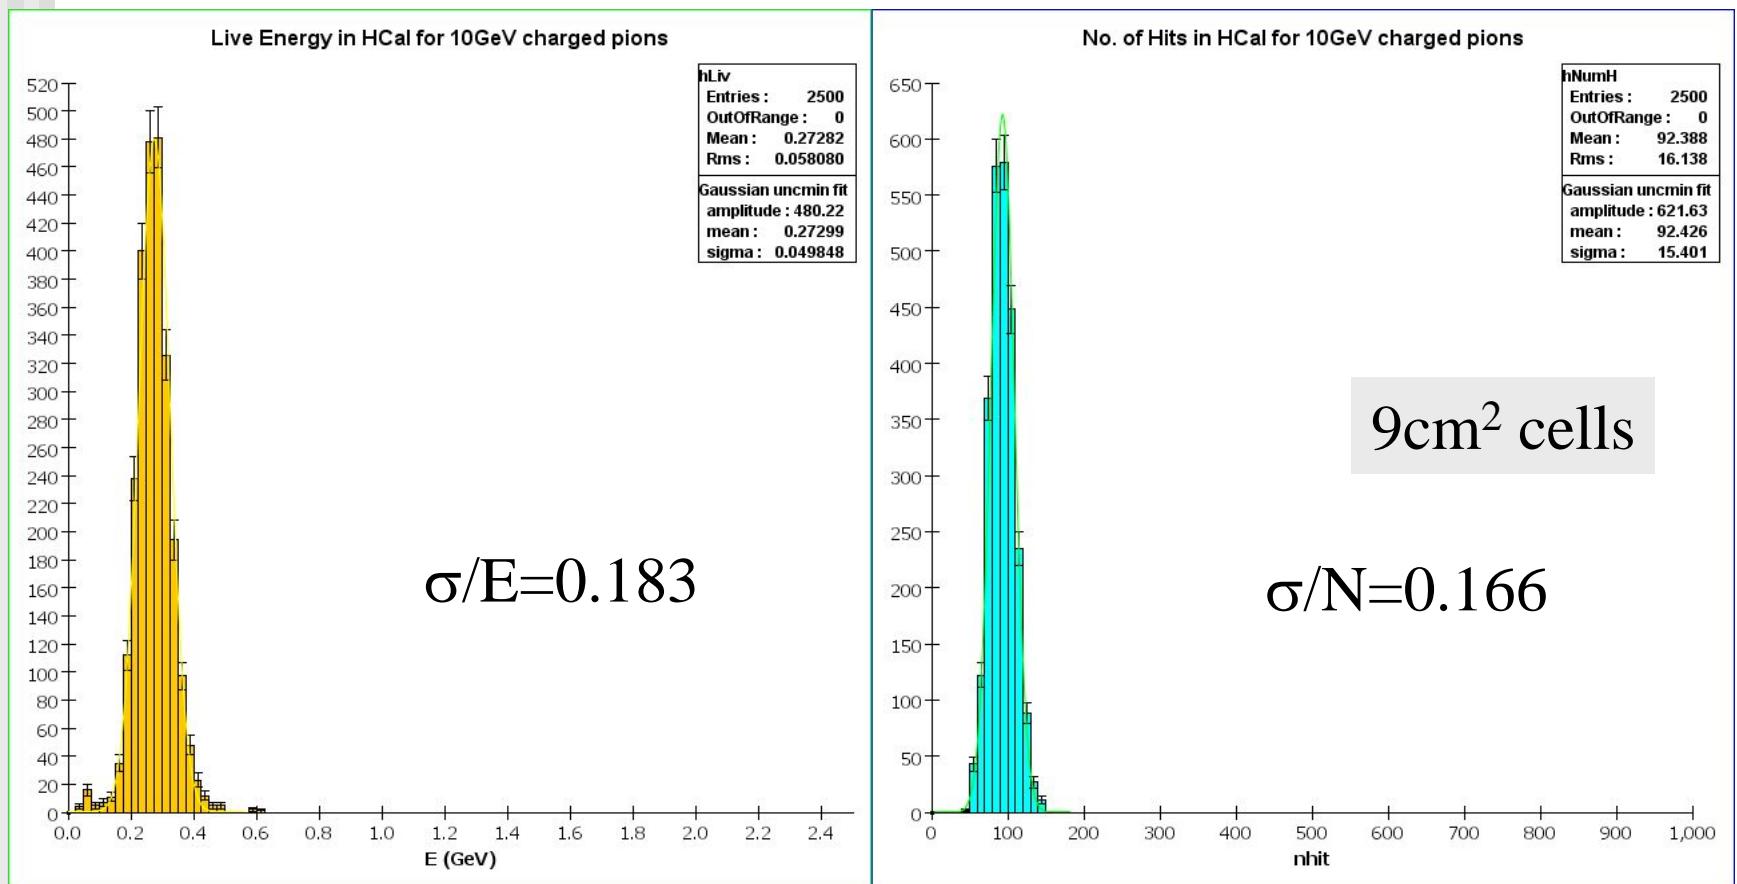

Number of cells hit by π^+ s of 2, 5, 10, 20, 30, 50 GeV

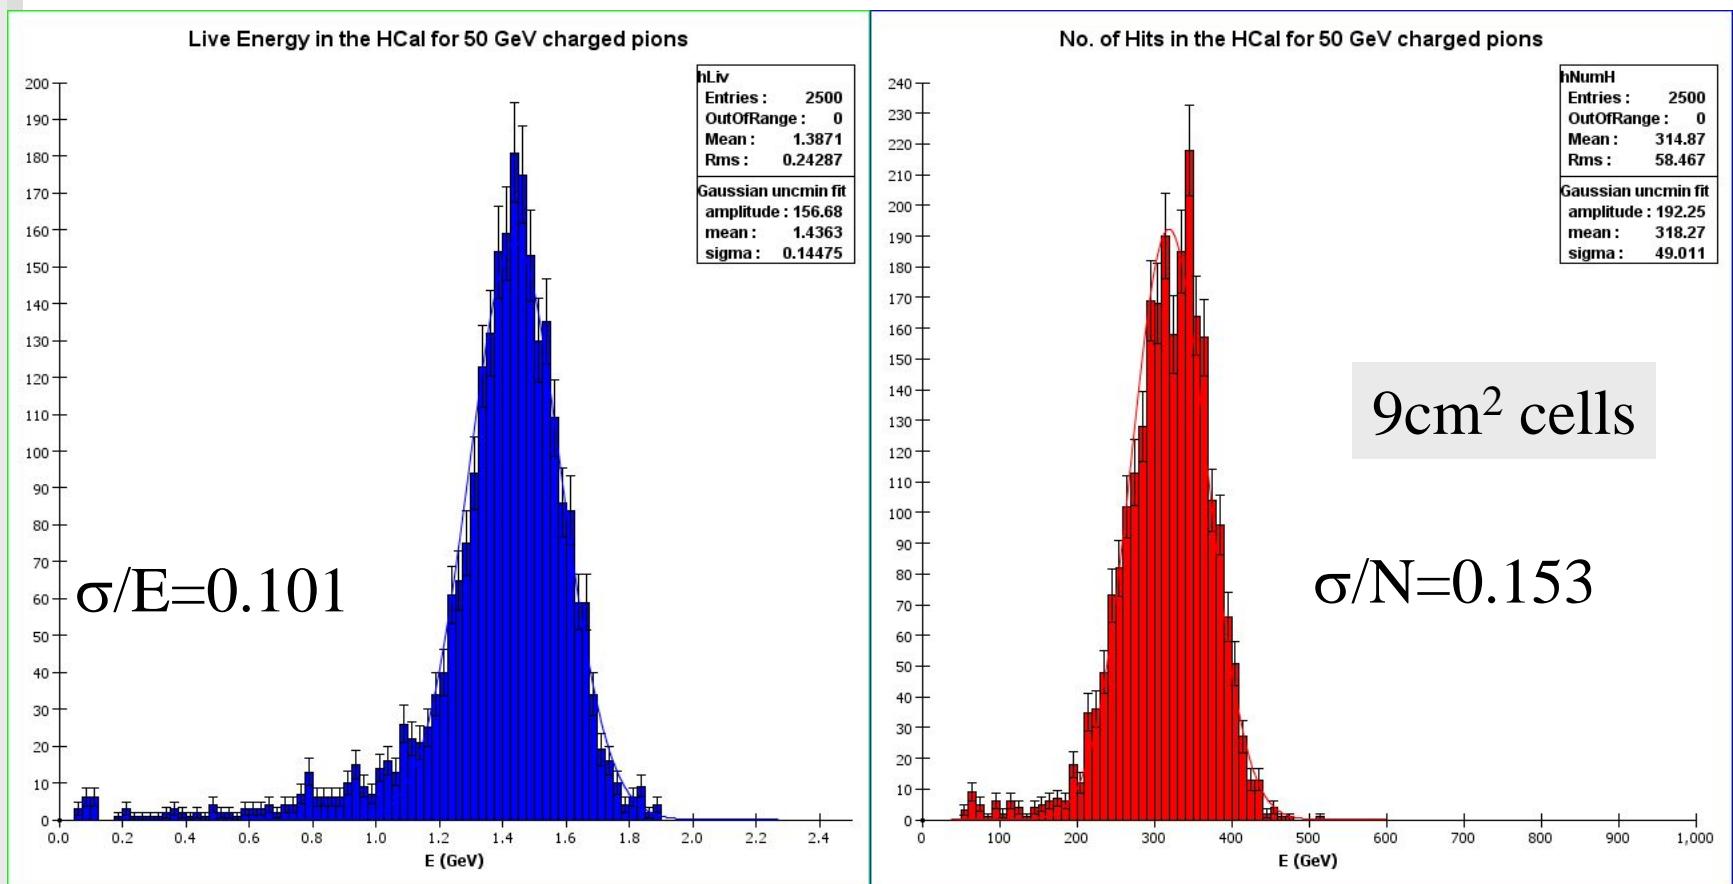

π^+ energy resolution as function of energy for different (linear) cell sizes

Energy resolution for 10 GeV π^+ s

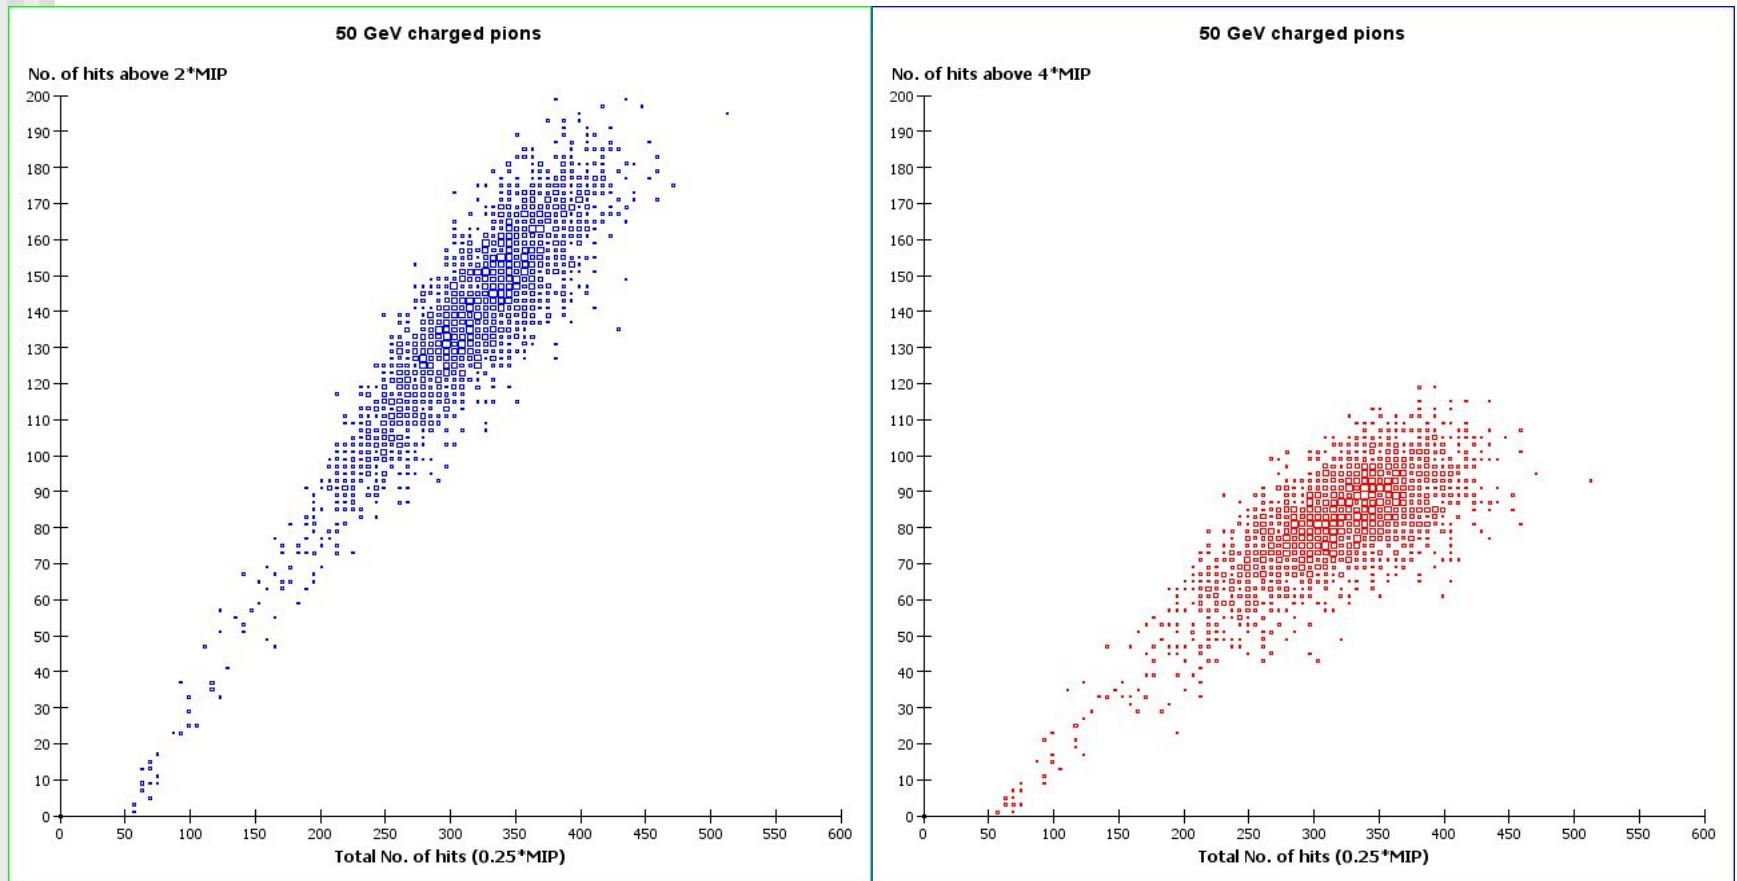

Energy resolution for 50 GeV π^+ s

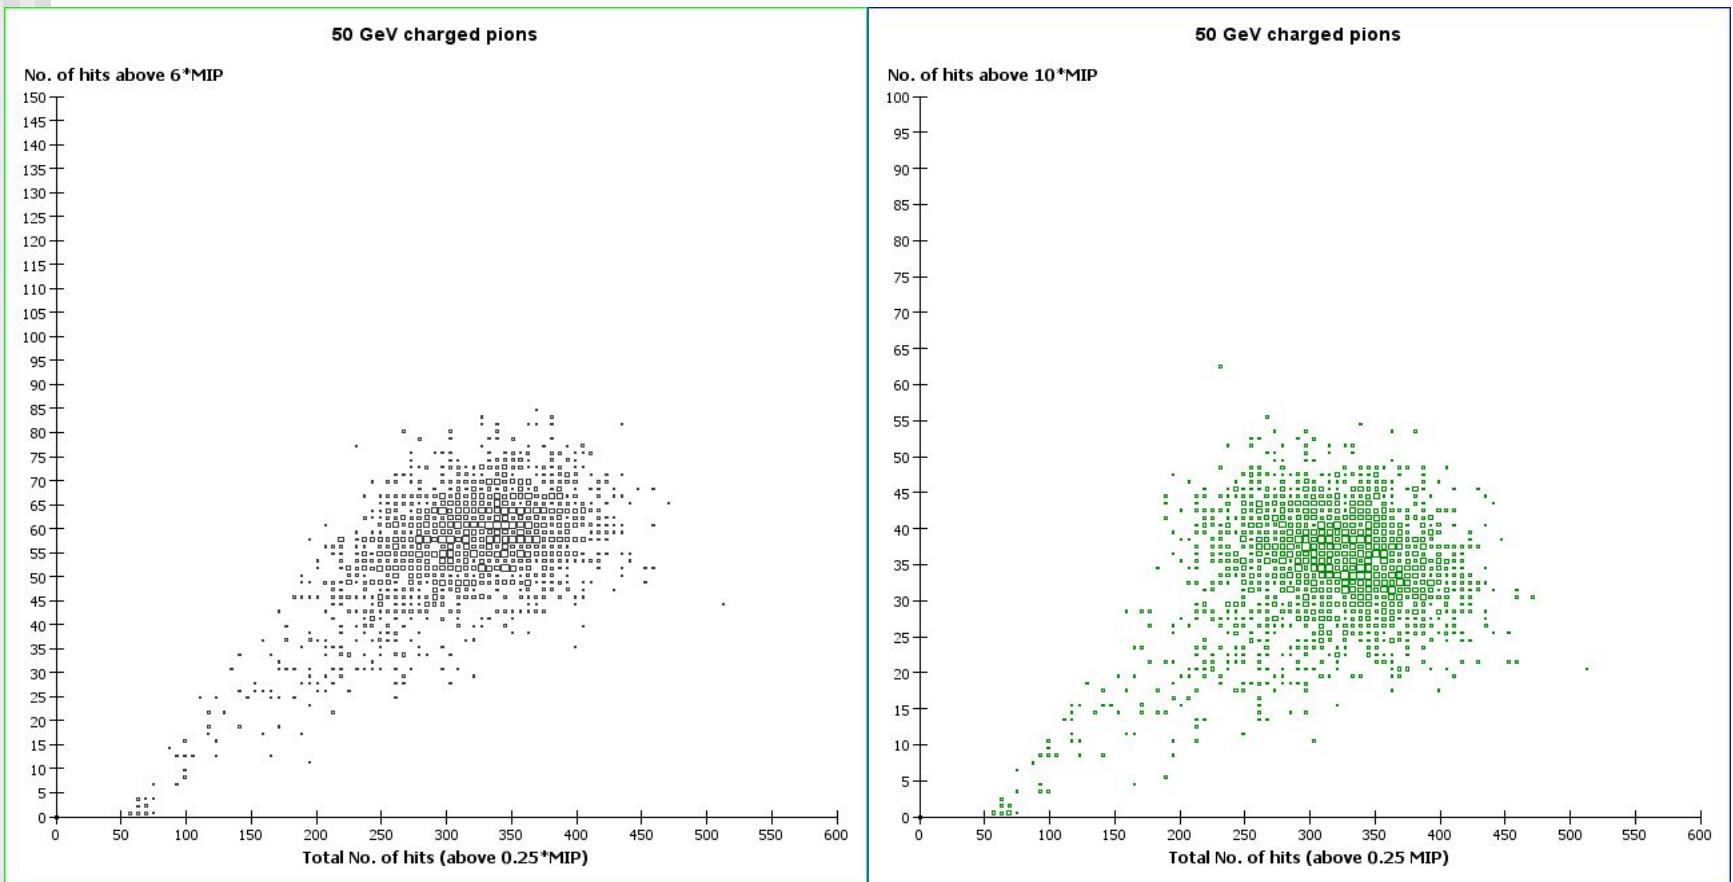

ILC LD meeting,
14-01-2005

Analog vs. Digital HCal for ILC

Nhit correlations for different cell energy thresholds

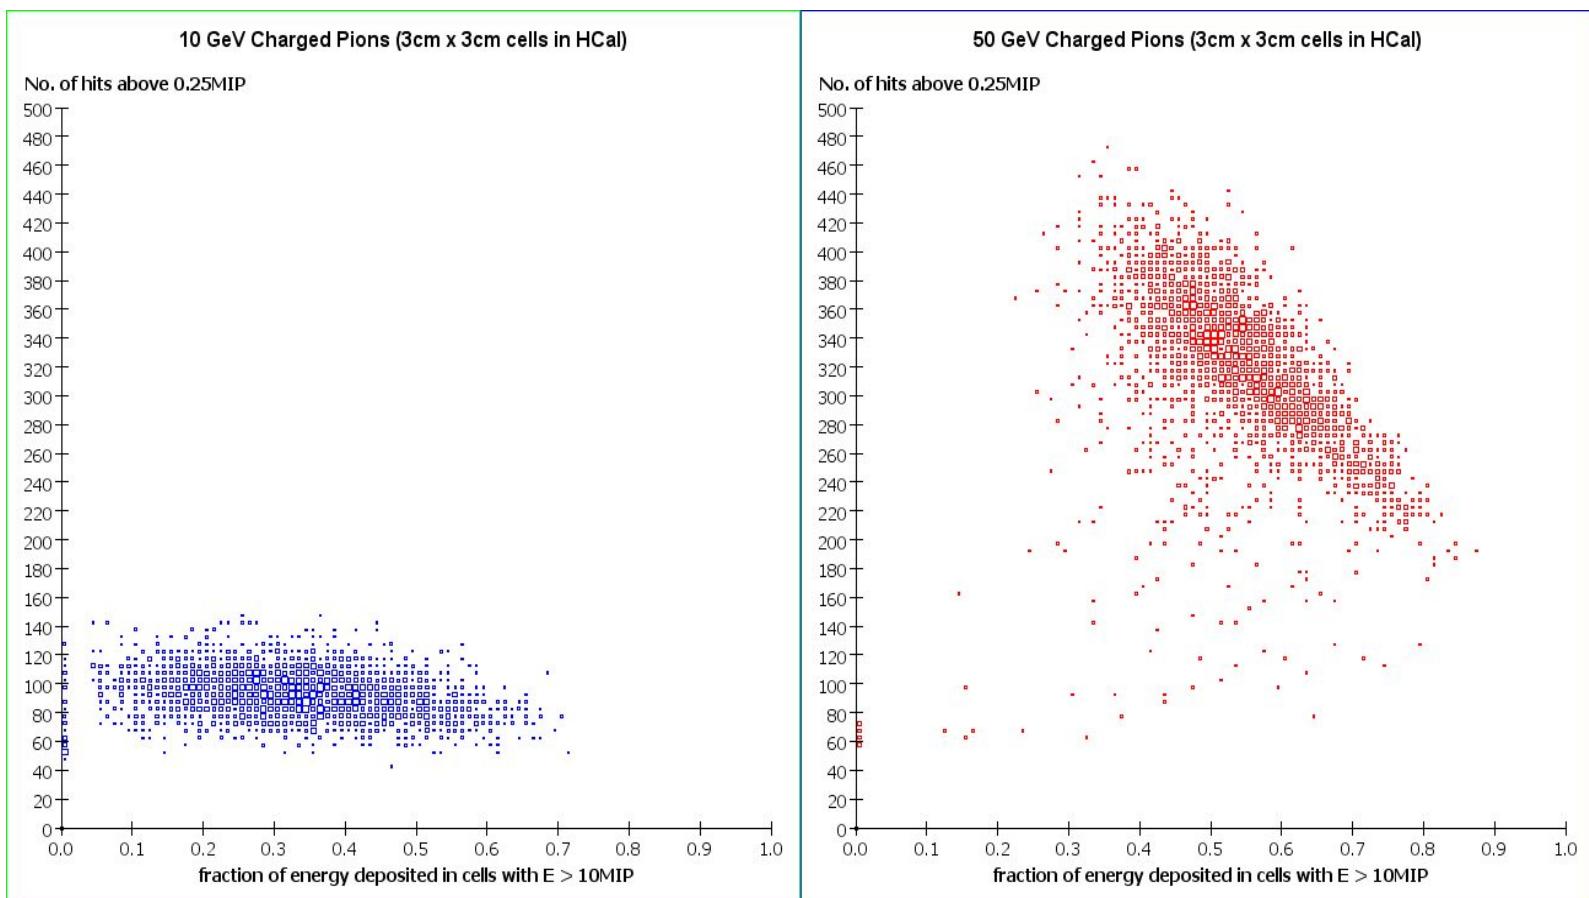

Nhit correlations for different cell energy thresholds

Nhit correlations for different cell energy thresholds

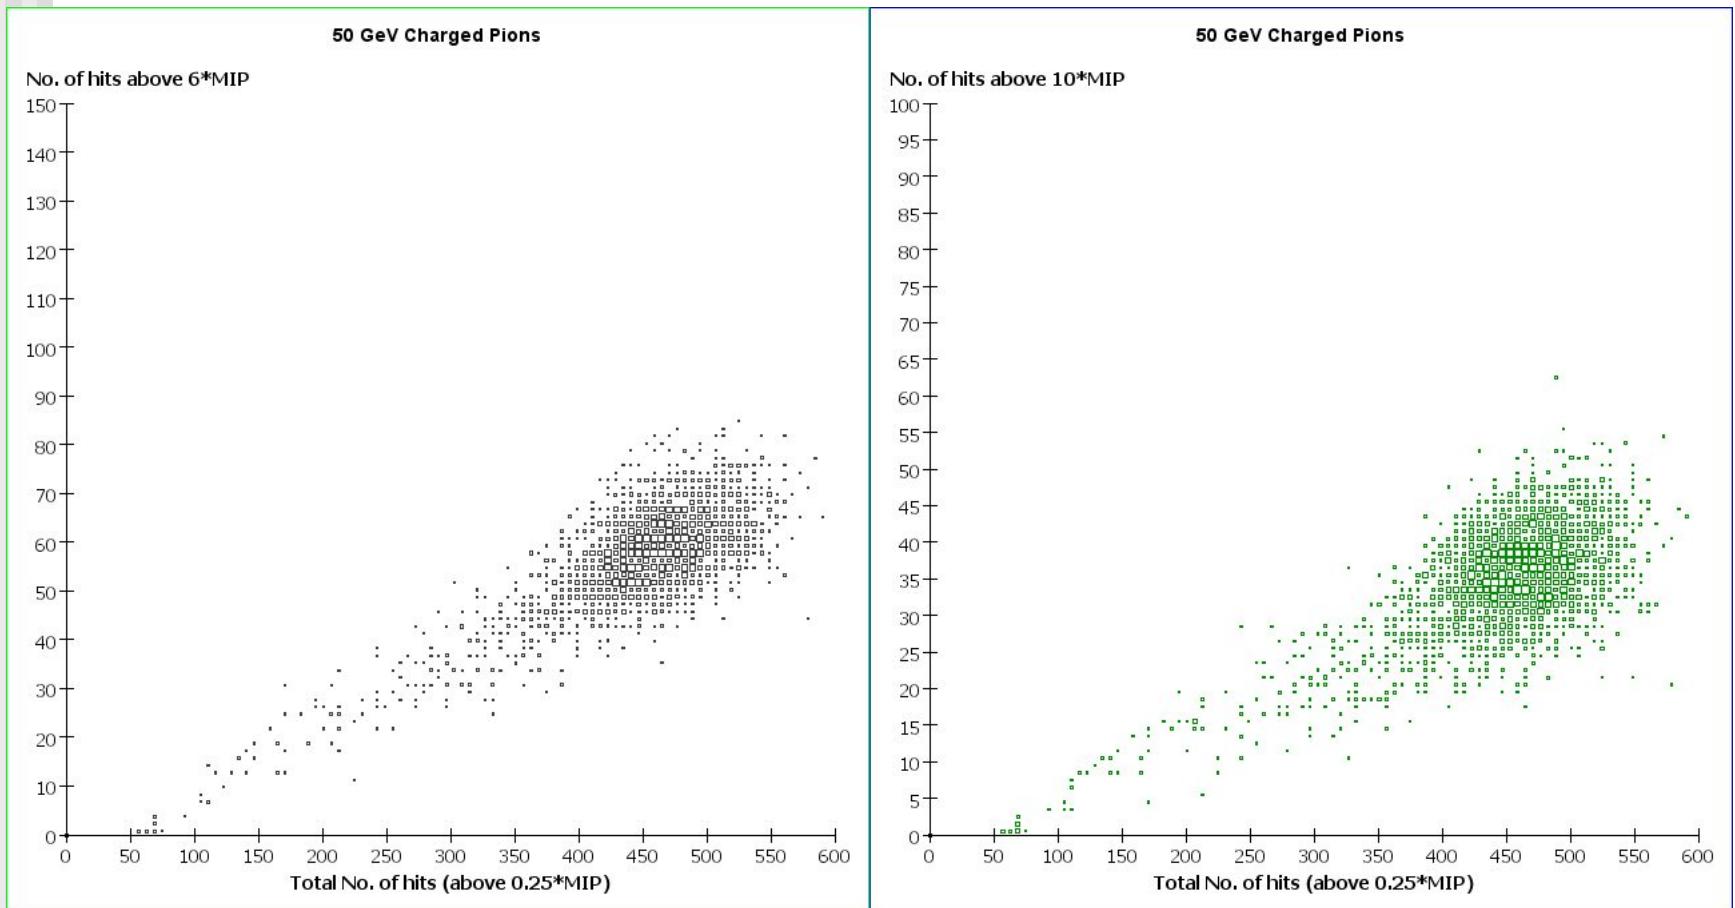

Alternatively,

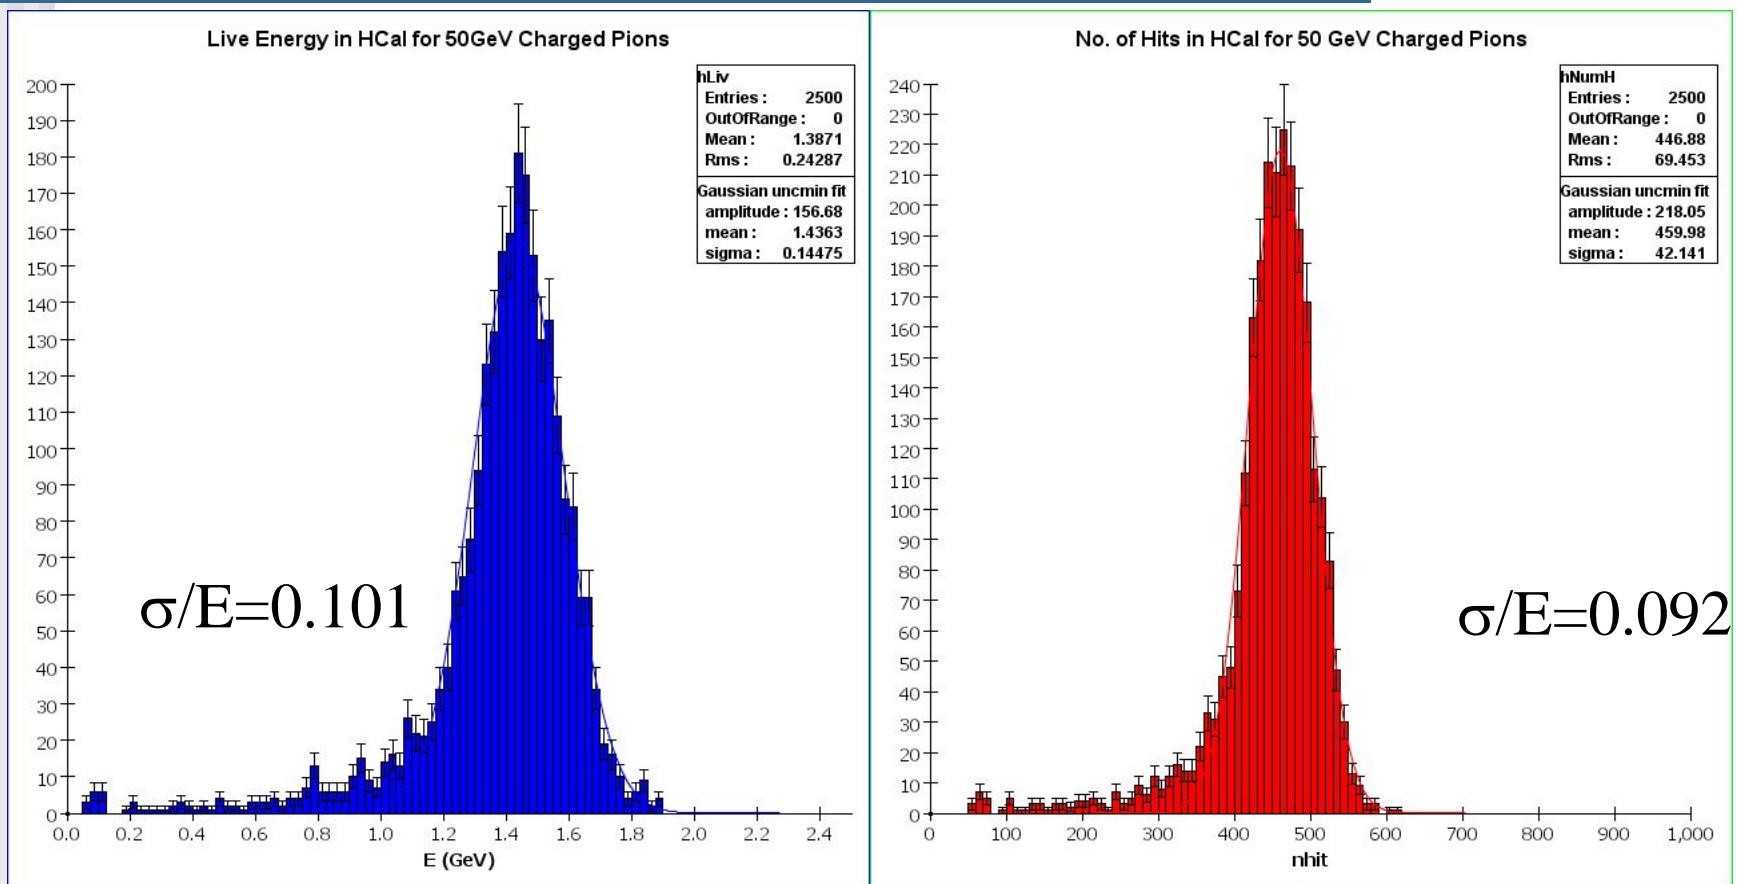

Compensation

- Cell counting has its own version of the compensation problem (in scintillators).
- With multiple threshold this can be overcome by weighting cells differently (according to the threshold they passed).
- In MC, 3 thresholds seem to be adequate

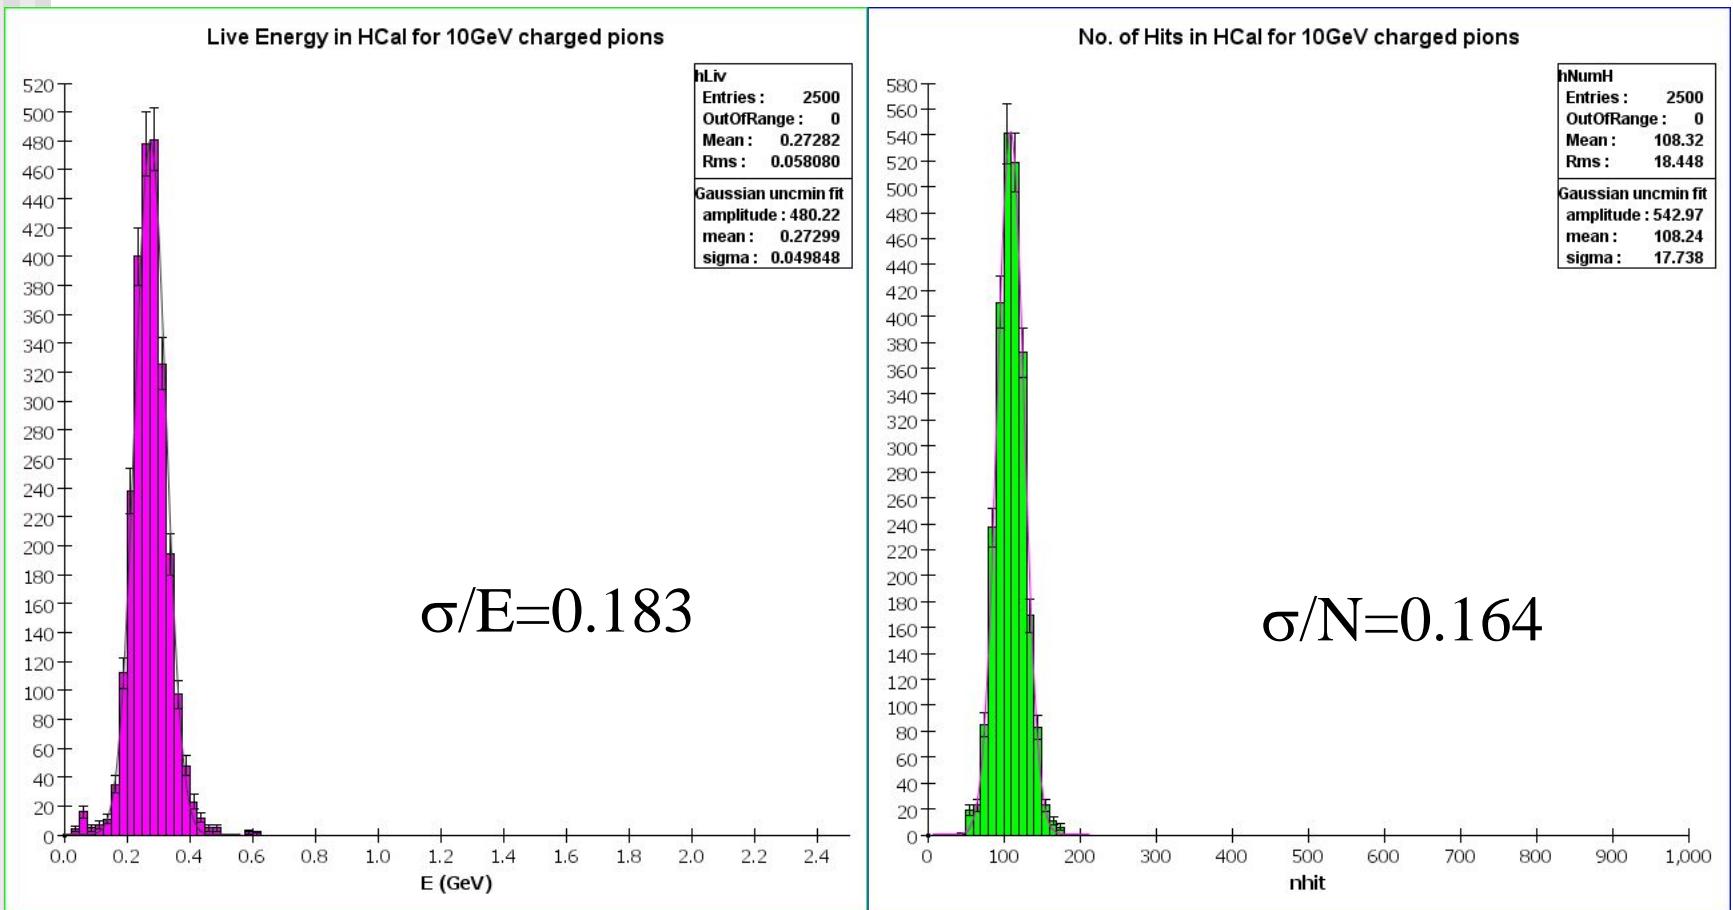

After semi-digital treatment

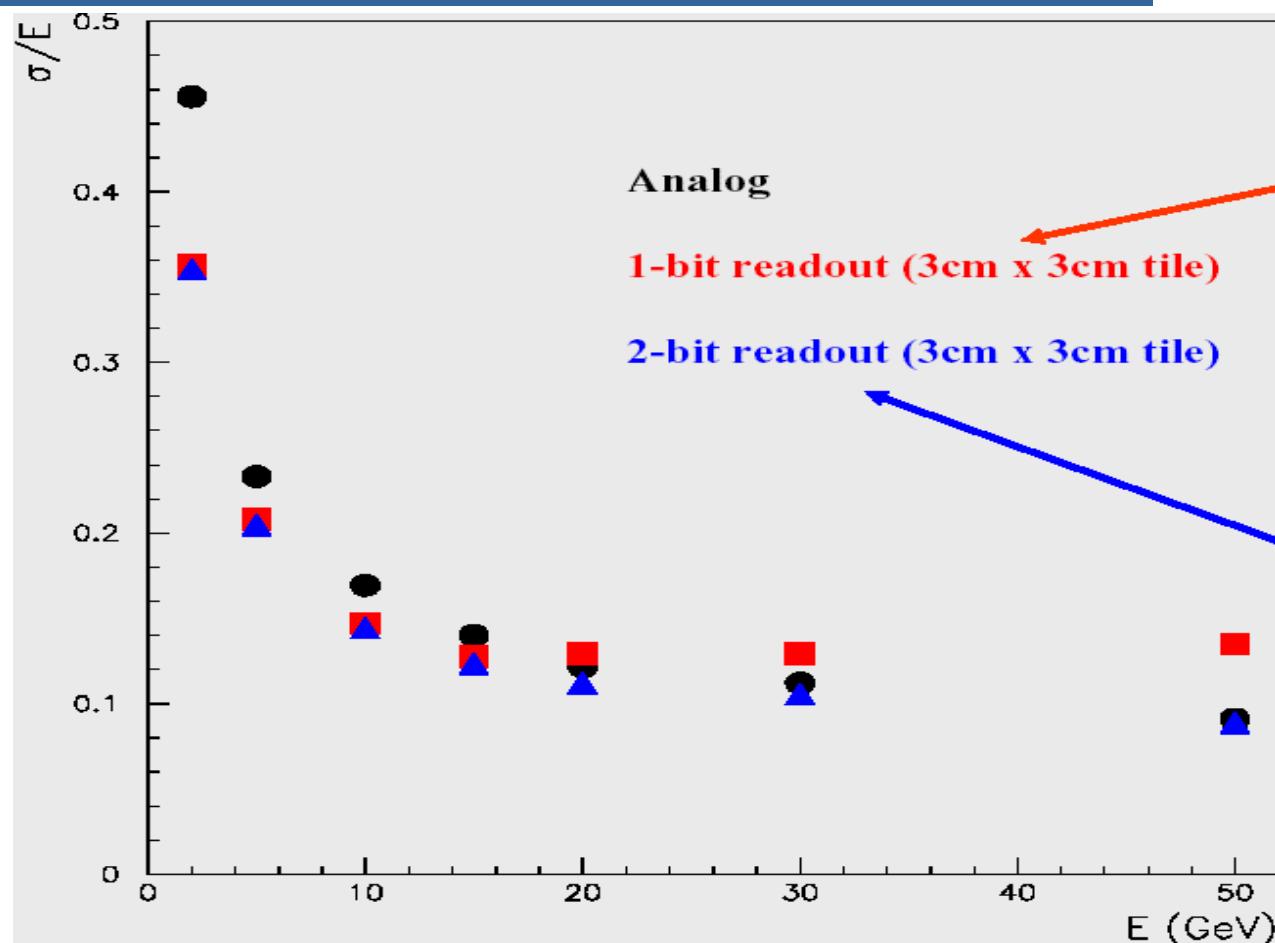

Energy resolution: 50 GeV π^+ s

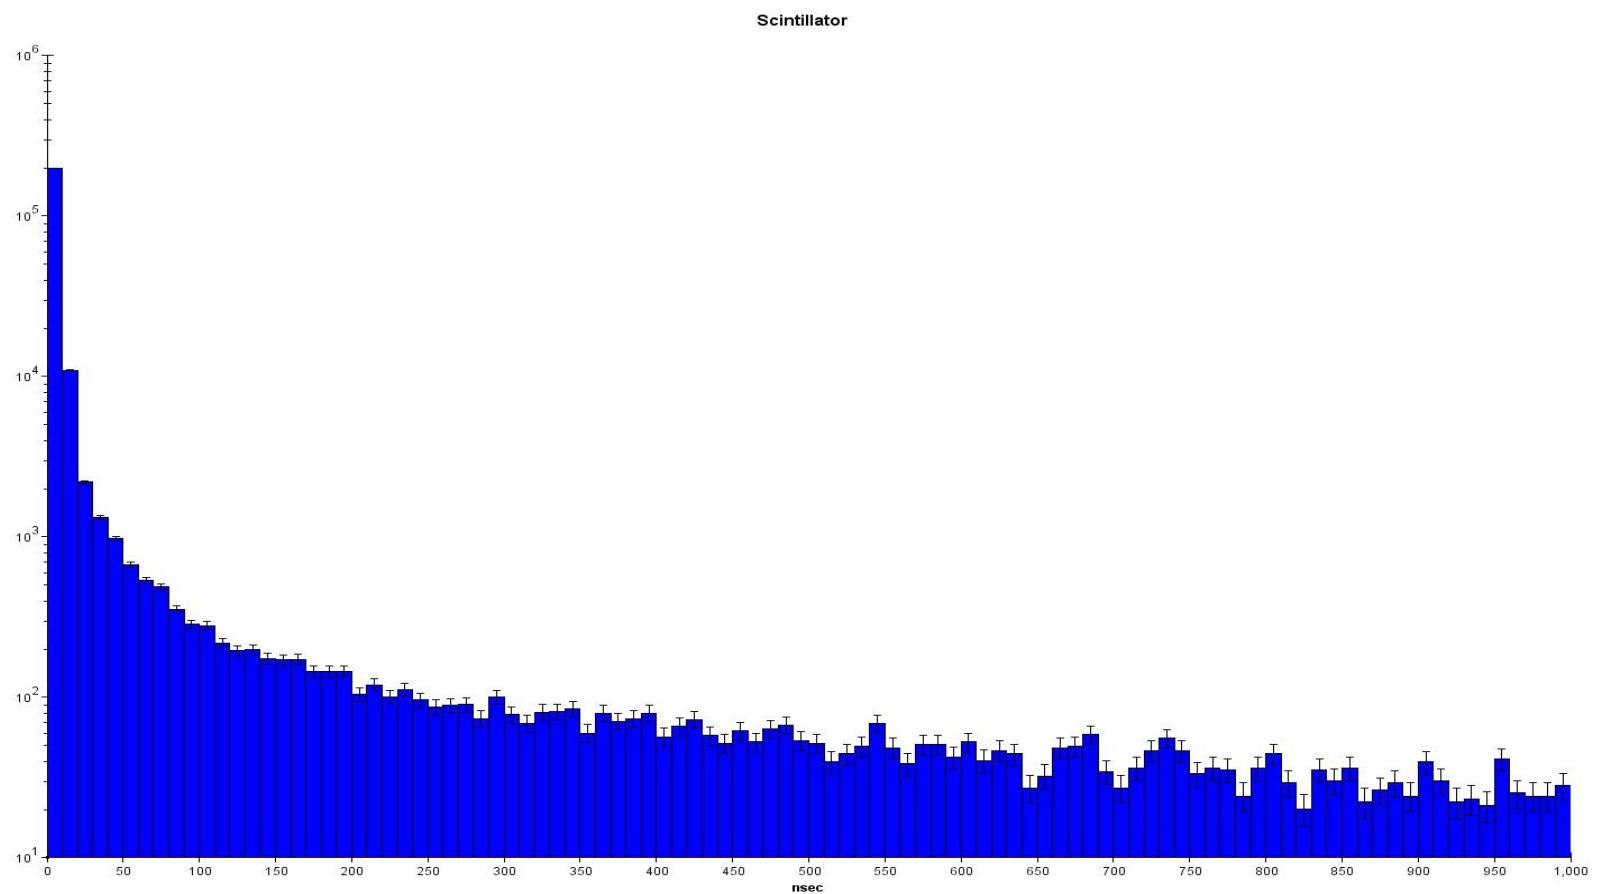

Energy resolution: 10 GeV π^+ s

π^+ energy resolution vs. energy

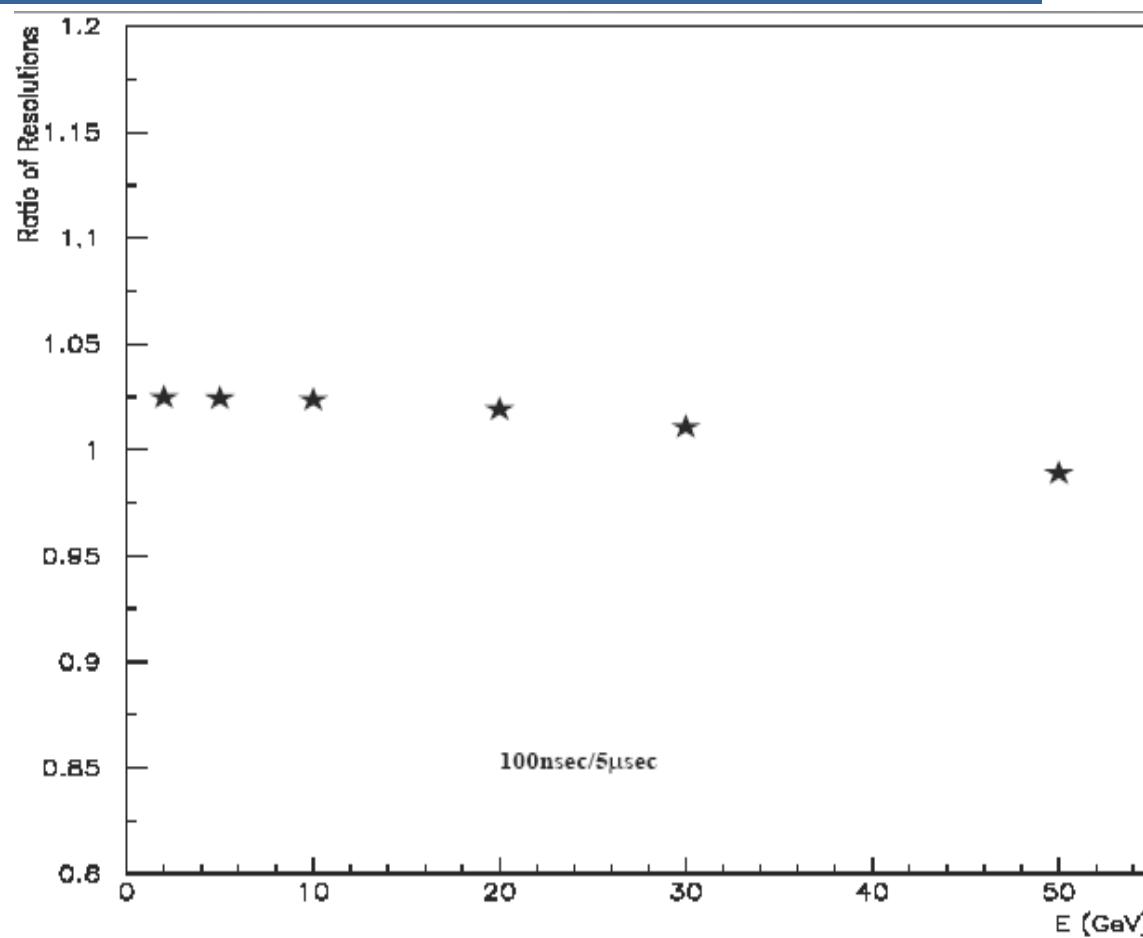

Time of flight

ToF dependence

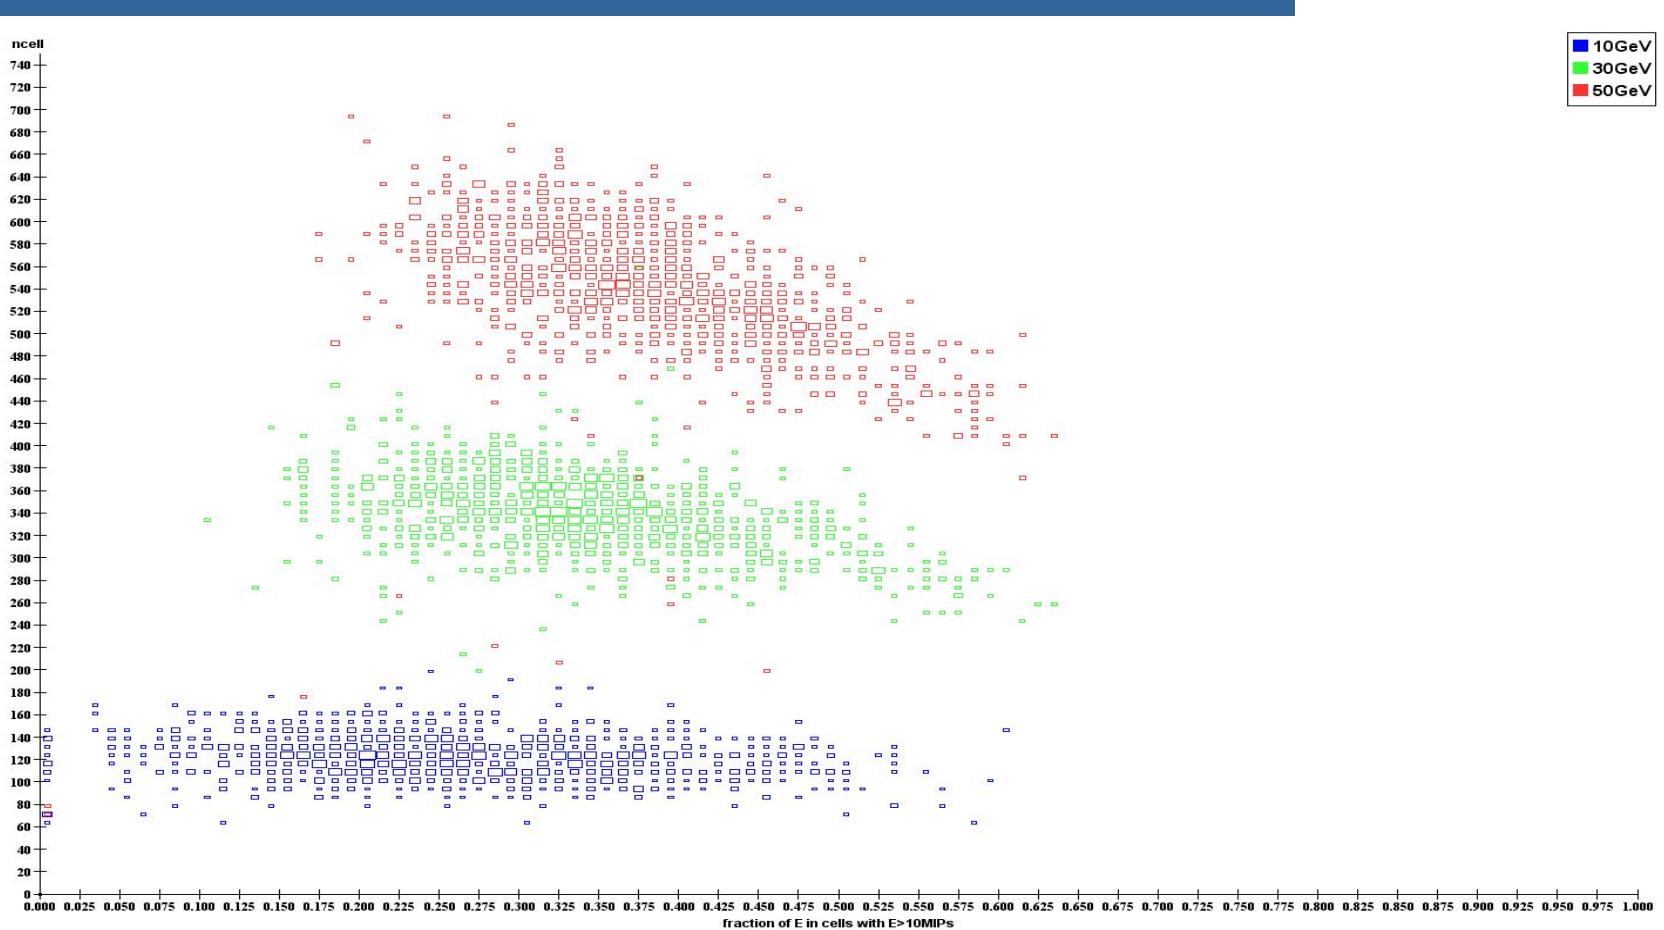

Cross-talk

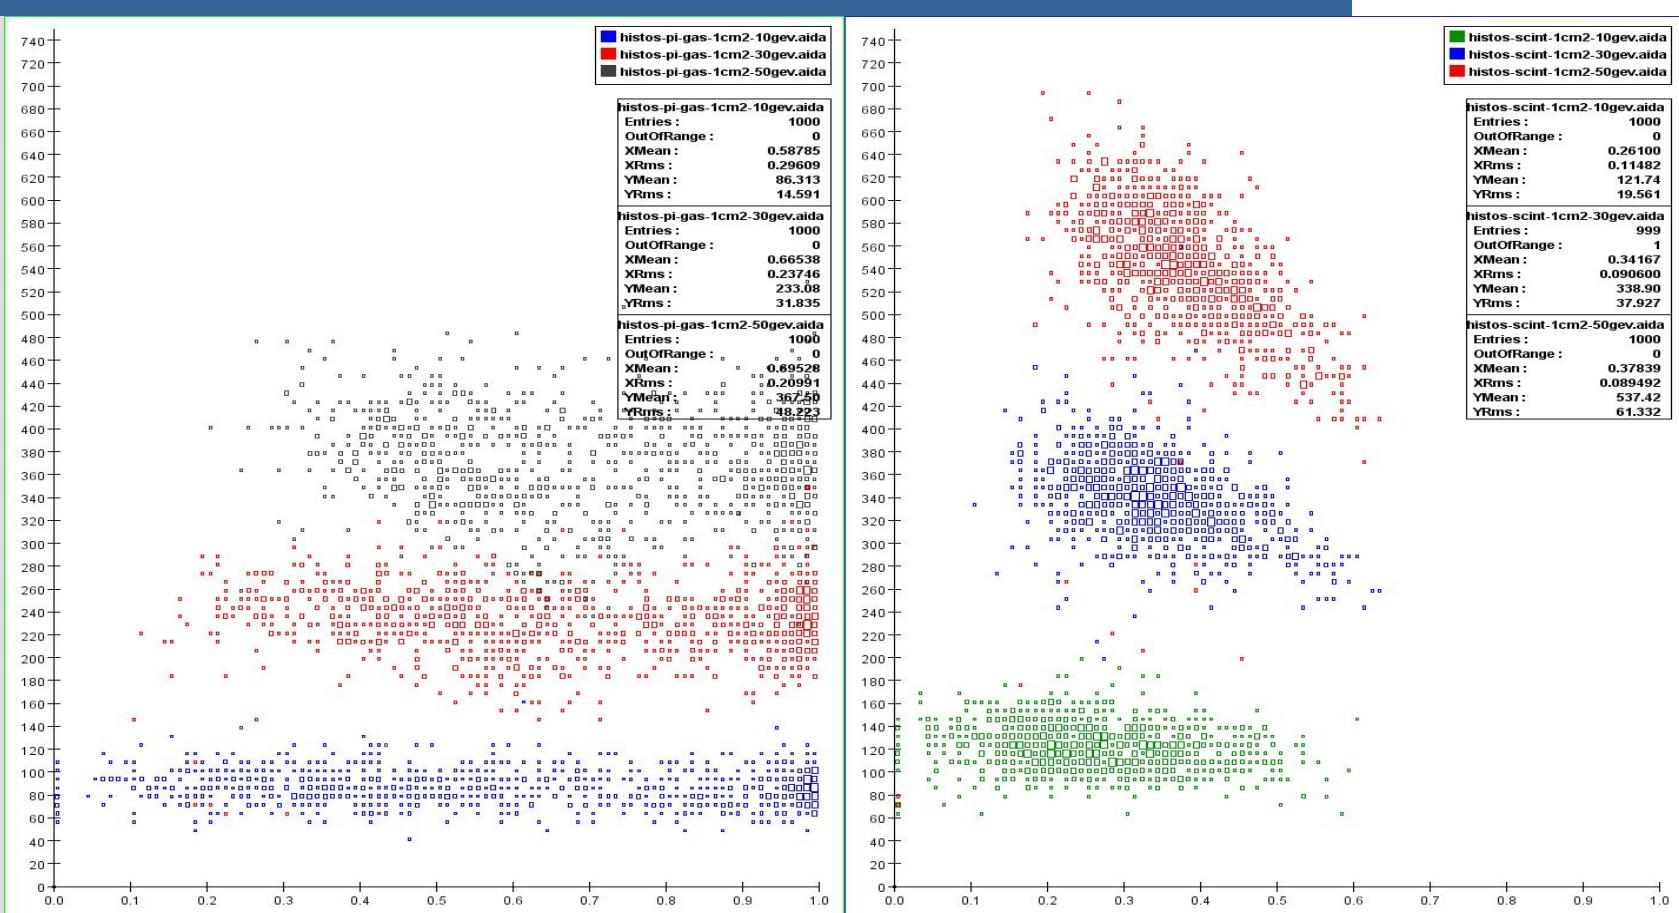

(10% of cell E leaks equally to 4 neighbors)

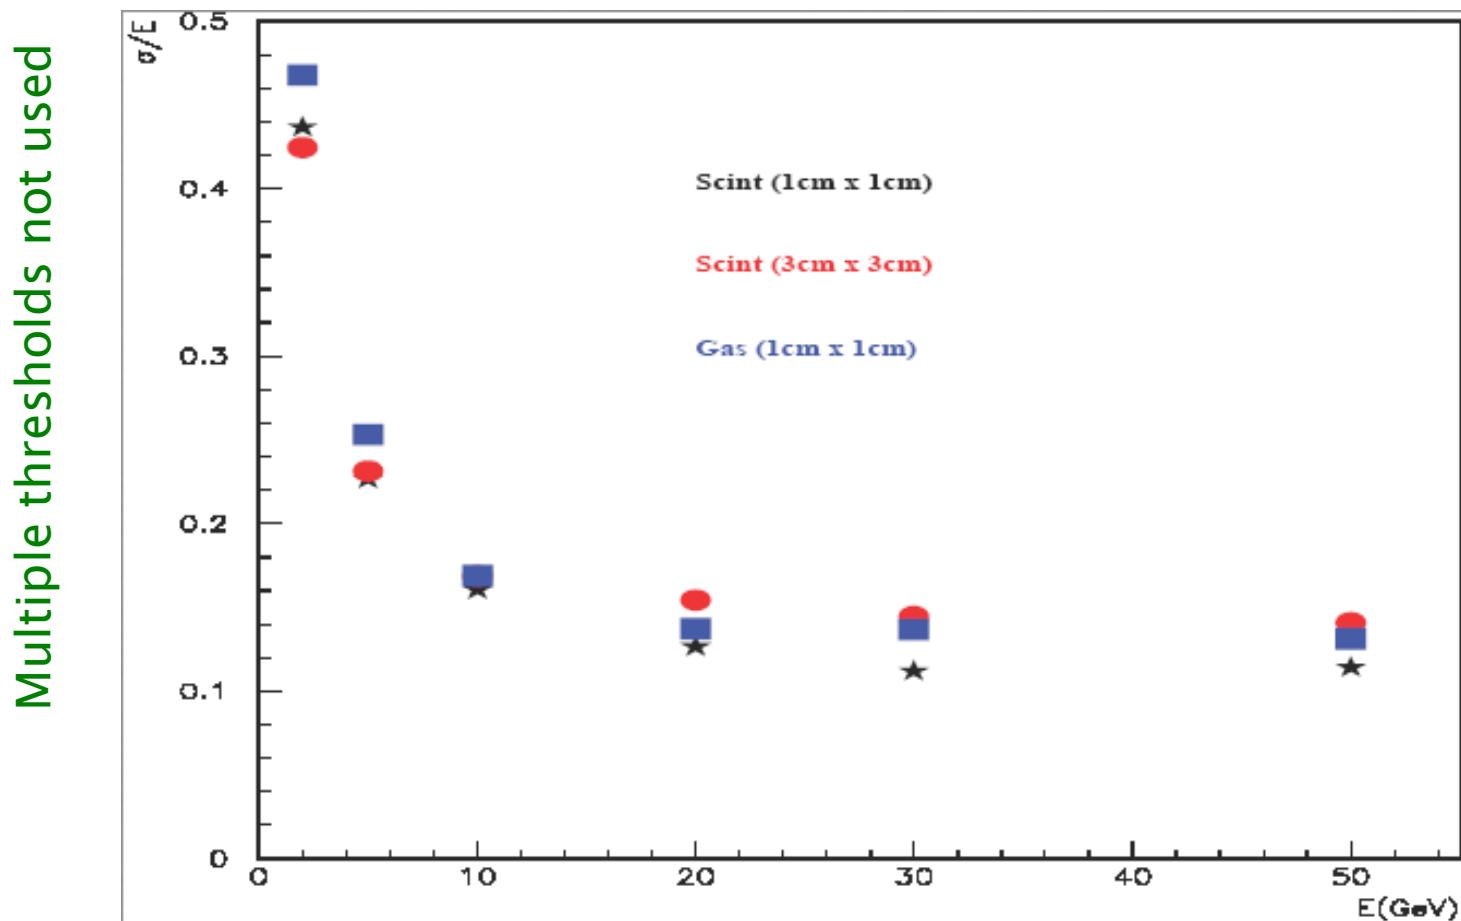

Nhit vs. fraction of π^+ E in cells with $E > 10$ MIP: 1cm x 1cm scintillator cells

Nhit vs. fraction of π^+ E in cells with $E > 10$ MIP: Gas vs. scintillator

π^+ energy resolution vs. energy

Non-linearity

- N_{hit}/GeV varies with energy.
- This will introduce additional pressure on the “constant” term.
- For scintillator the non-linearity can be effectively removed by “semi-digital” treatment.

Density of hits

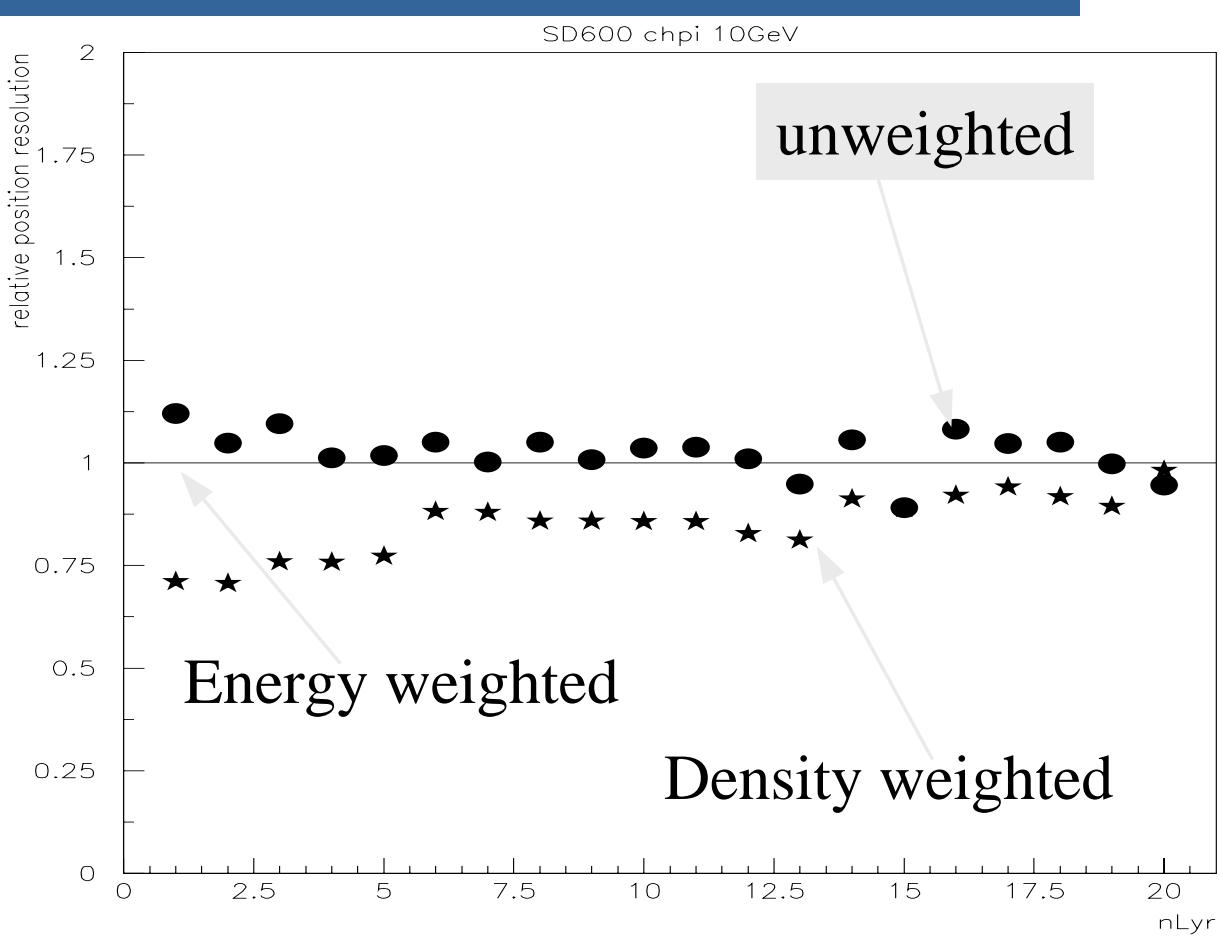

- Need a hierarchy in the absence of an energy measurement
- Local density of hits is an obvious candidate.
- A simple-minded density variable:

$$d_i = \sum (1/R_{ij}),$$

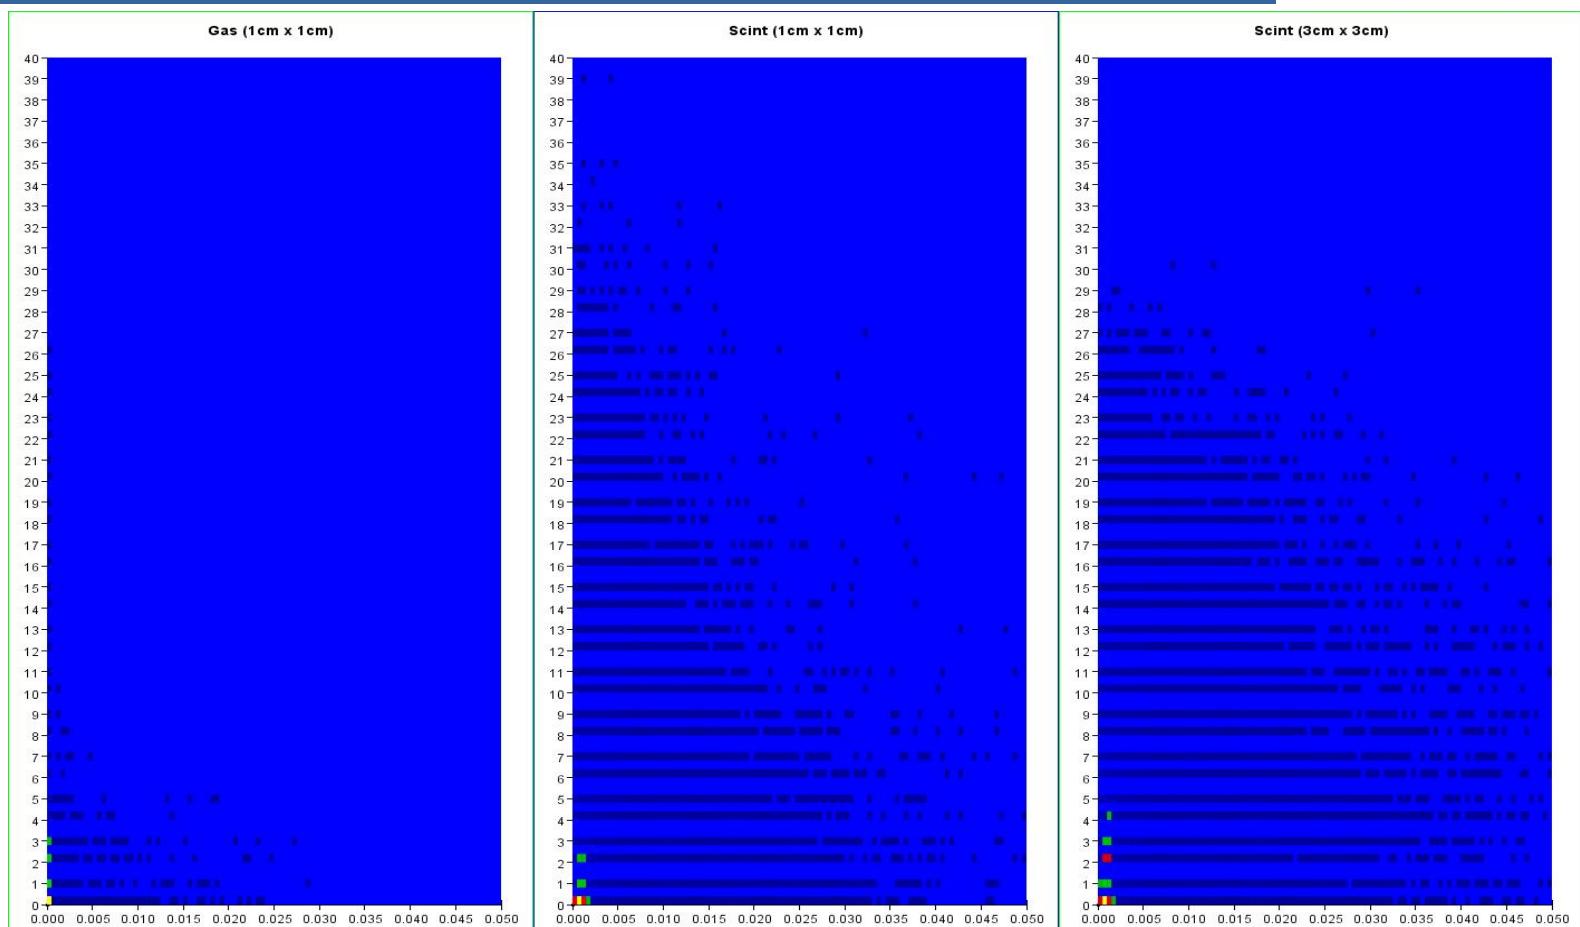

where R_{ij} is the angular distance between cells i & j.

Position resolution

Measured relative to the energy weighted resolutions

Density vs. Energy

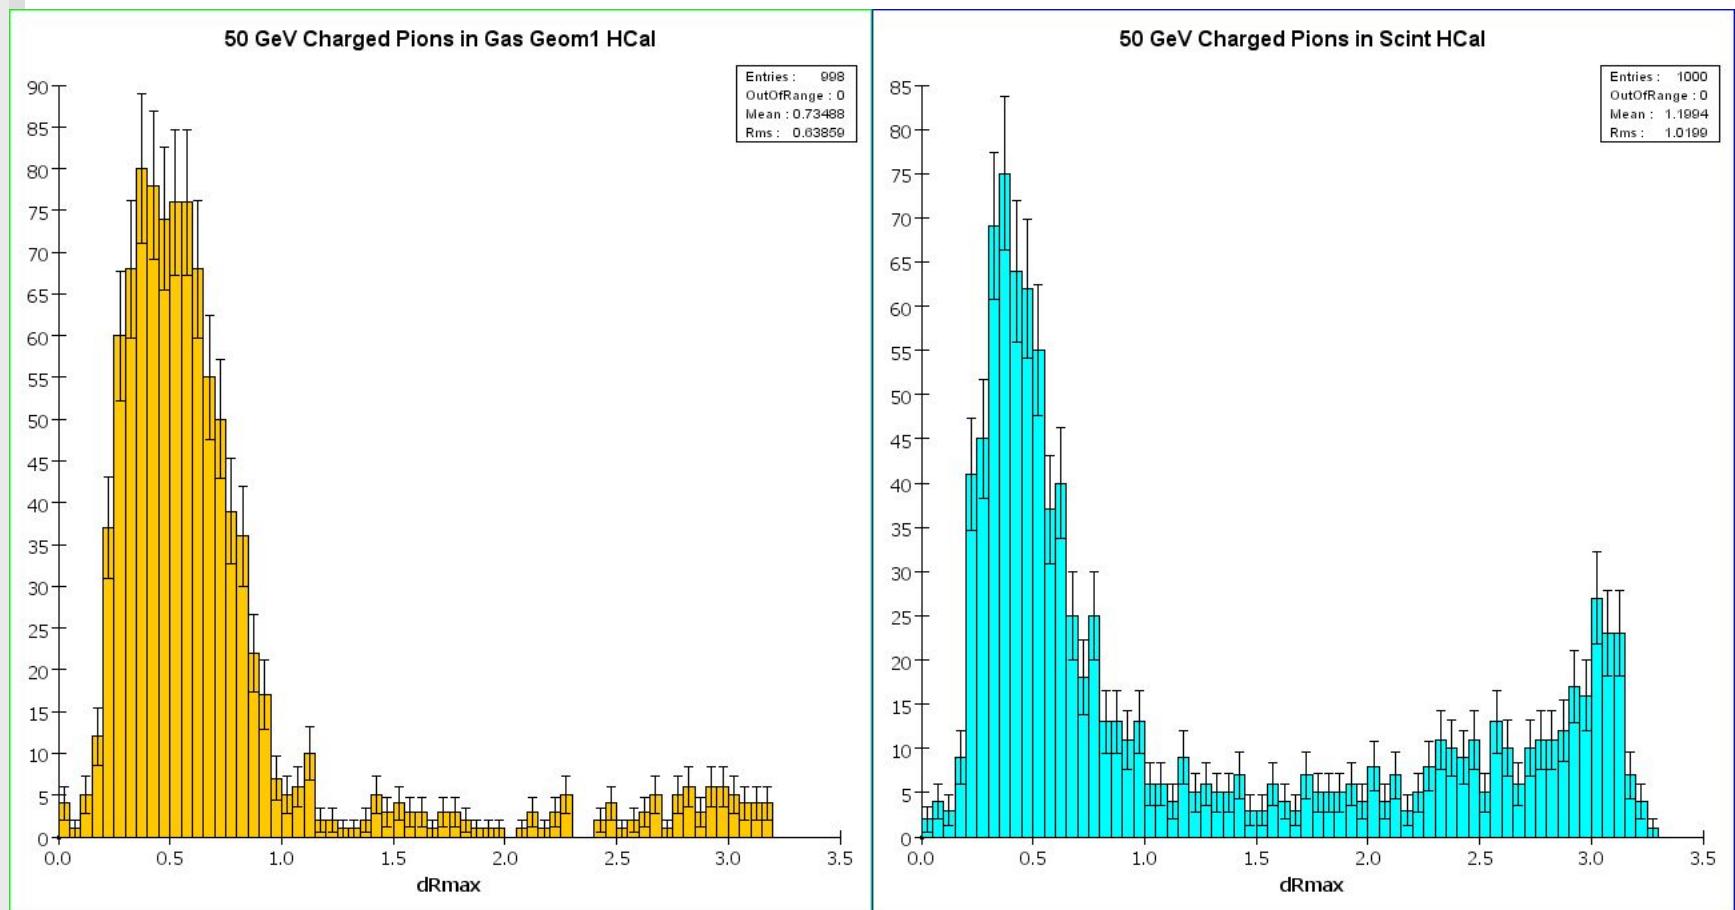

ILC LD meeting,

Analog vs. Digital HCal for ILC
Dhiman Chakraborty

Width

- Find centroid $\{\sum w_i x_i / \sum w_i\}$
- 'width' = $\sqrt{\sum w_i R_i^2 / \sum w_i}$
- Three weights were used:
 - Unweighted ($w_i=1$)
 - Energy weighted ($w_i=E_i$)
 - Density weighted ($w_i=\text{nearest-neighbor occupancy in a } 5\times 5 \text{ window in lyrs } k-1, k, k+1$)

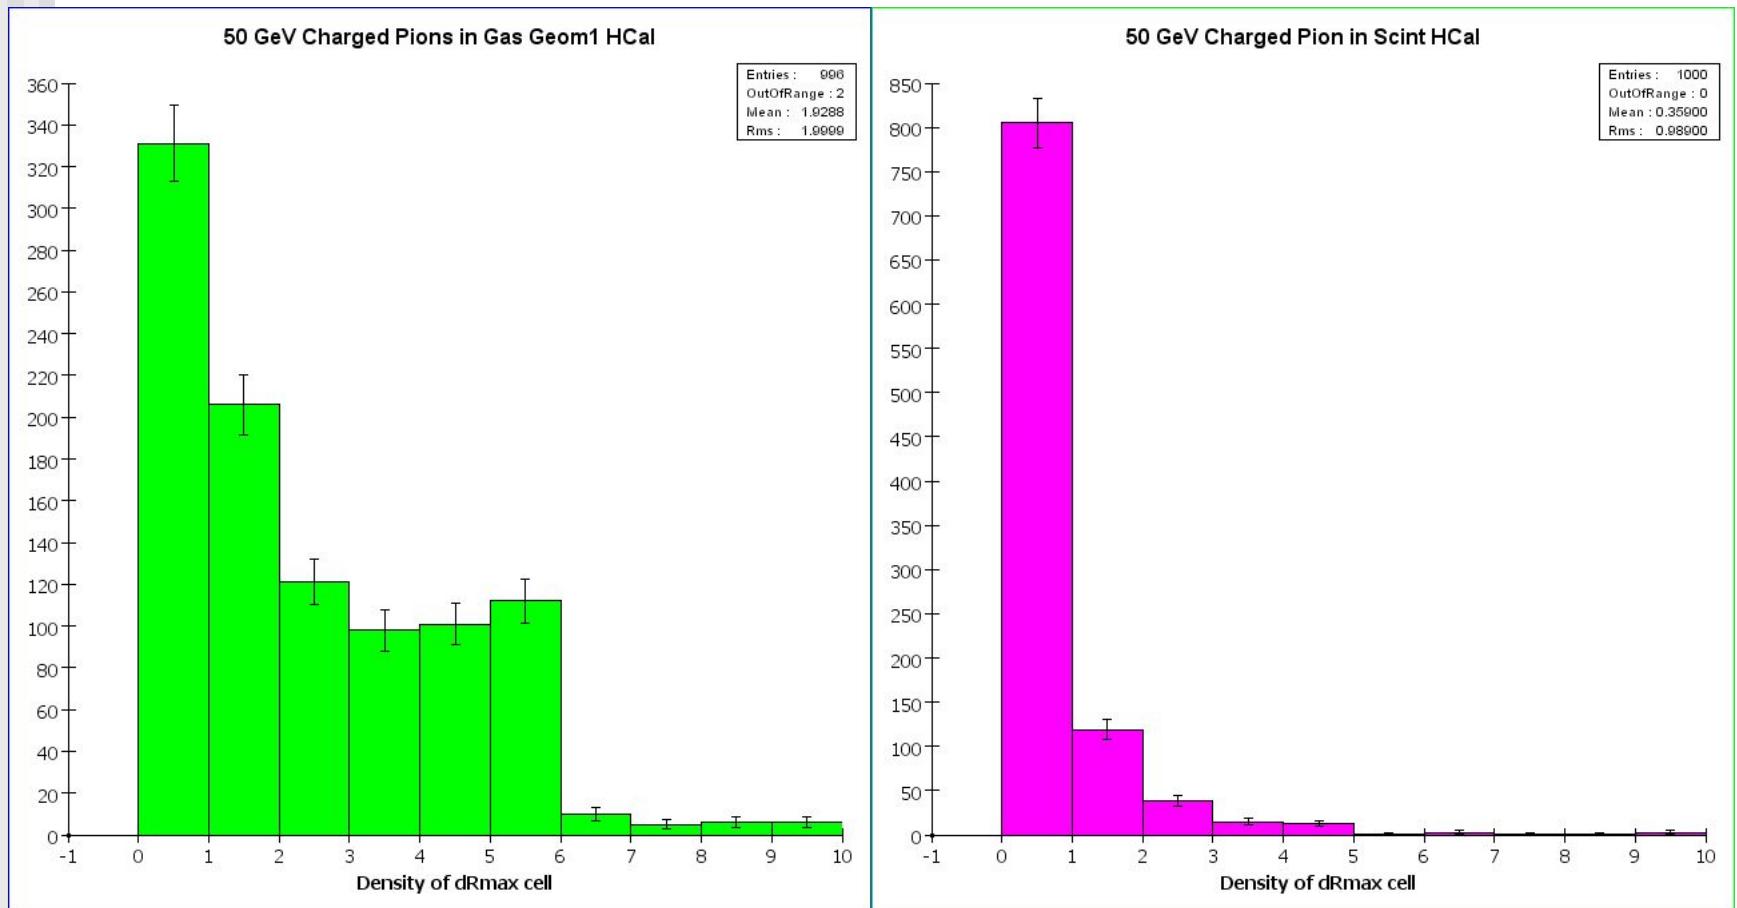

Distance to farthest cell

π^\pm angular width

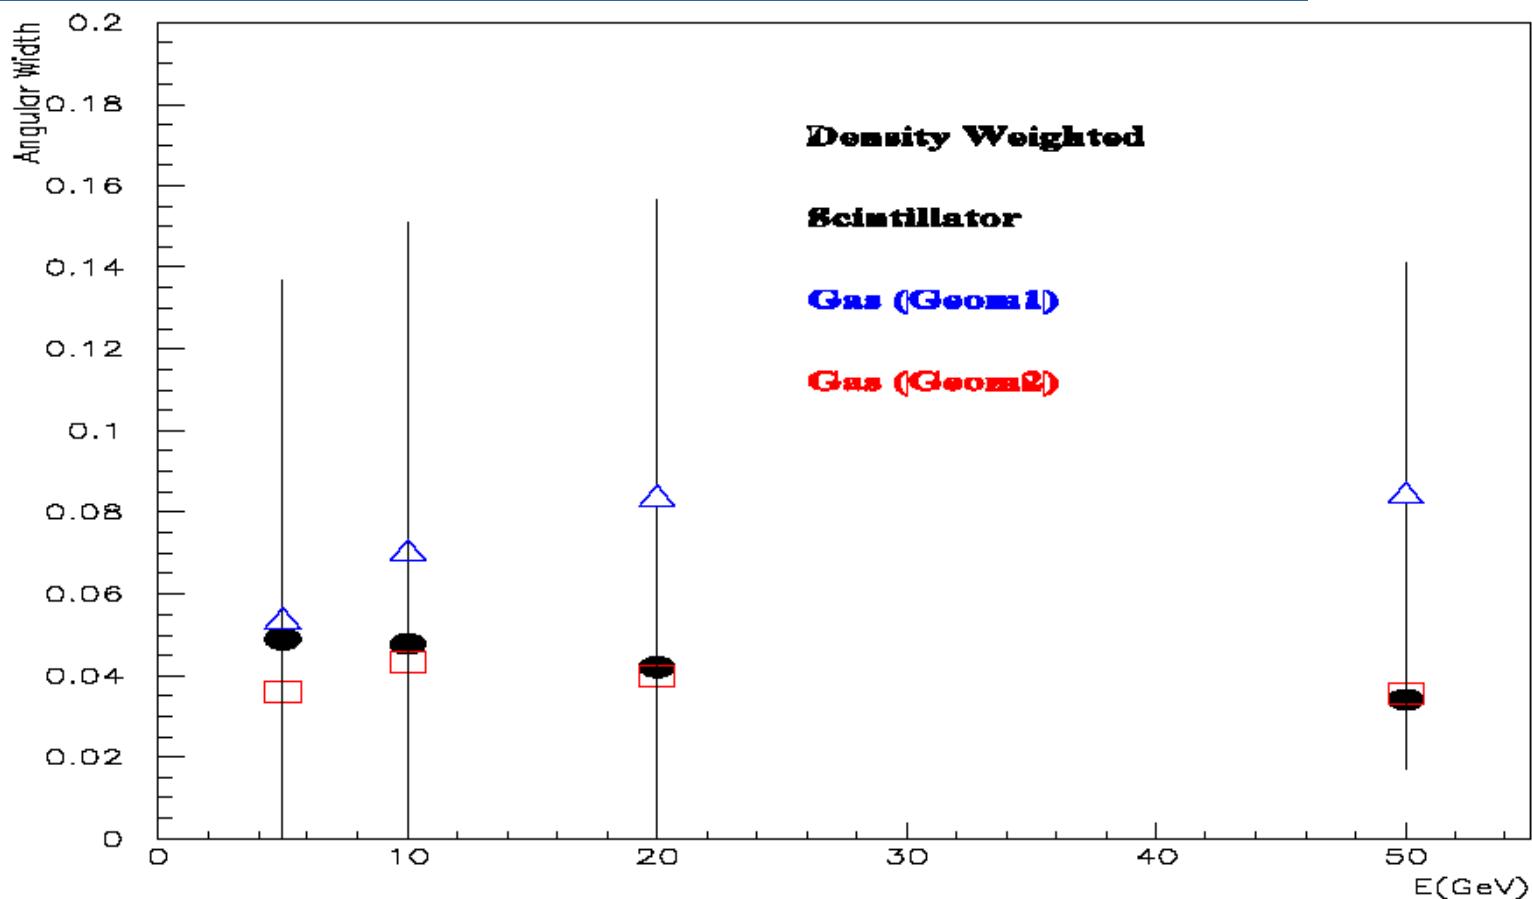

rms shown as bars

π^\pm angular width: energy weighted

π^\pm angular width: density weighted

Comments

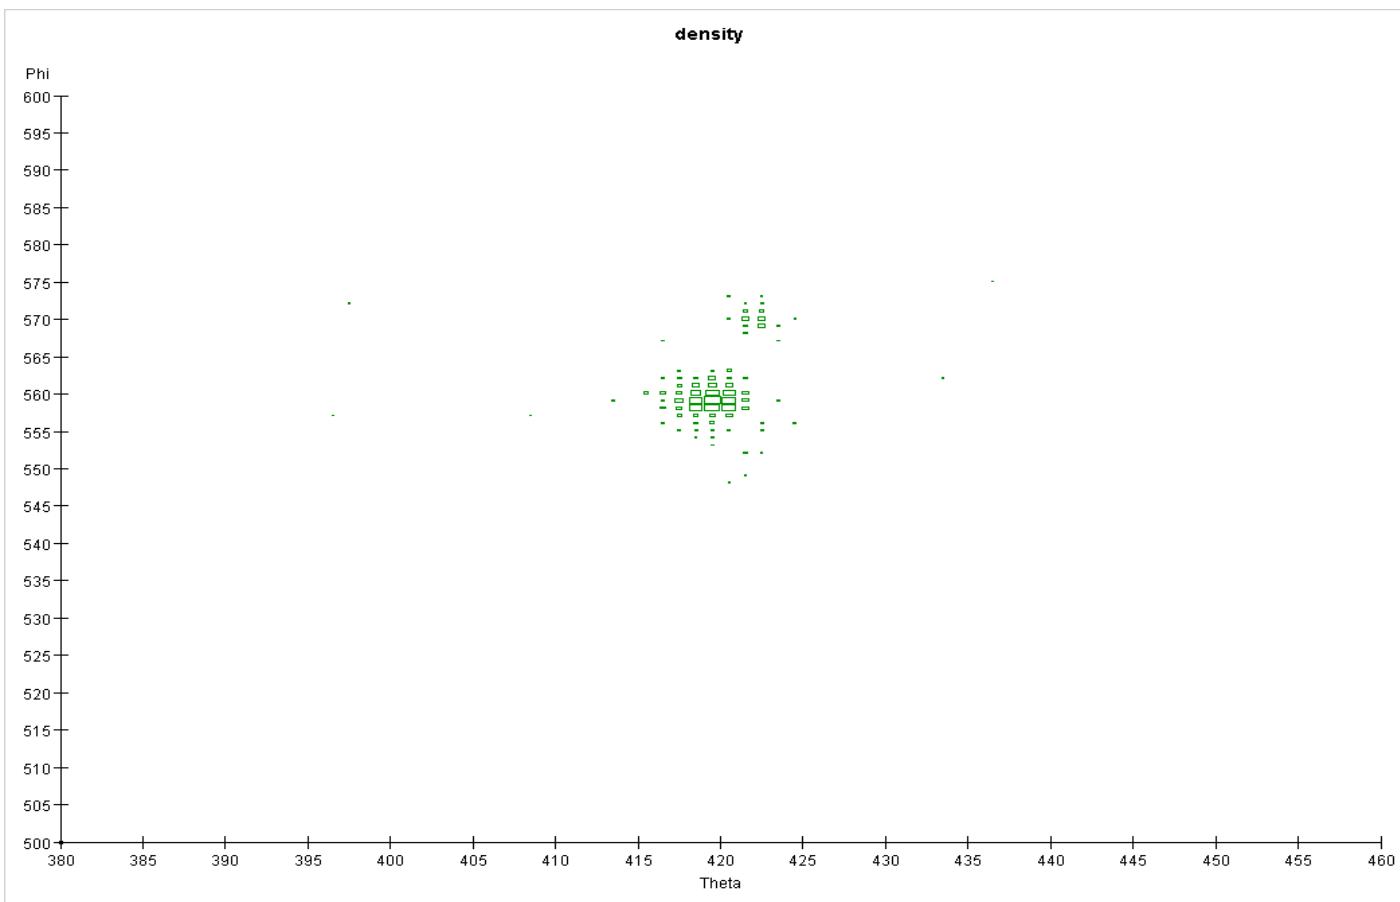

- There is no clear cut case either way at the moment; detailed studies of assessing impact needed.
- Will look at cluster separability next.
- Need to evaluate this in the global context of calorimeter performance.

Clustering

- Clustering based on local density works well.
- It is an alternative to track-seeded clustering.
- Can be used in the ECal and HCal.
- Full PFlow implementation gives encouraging results.

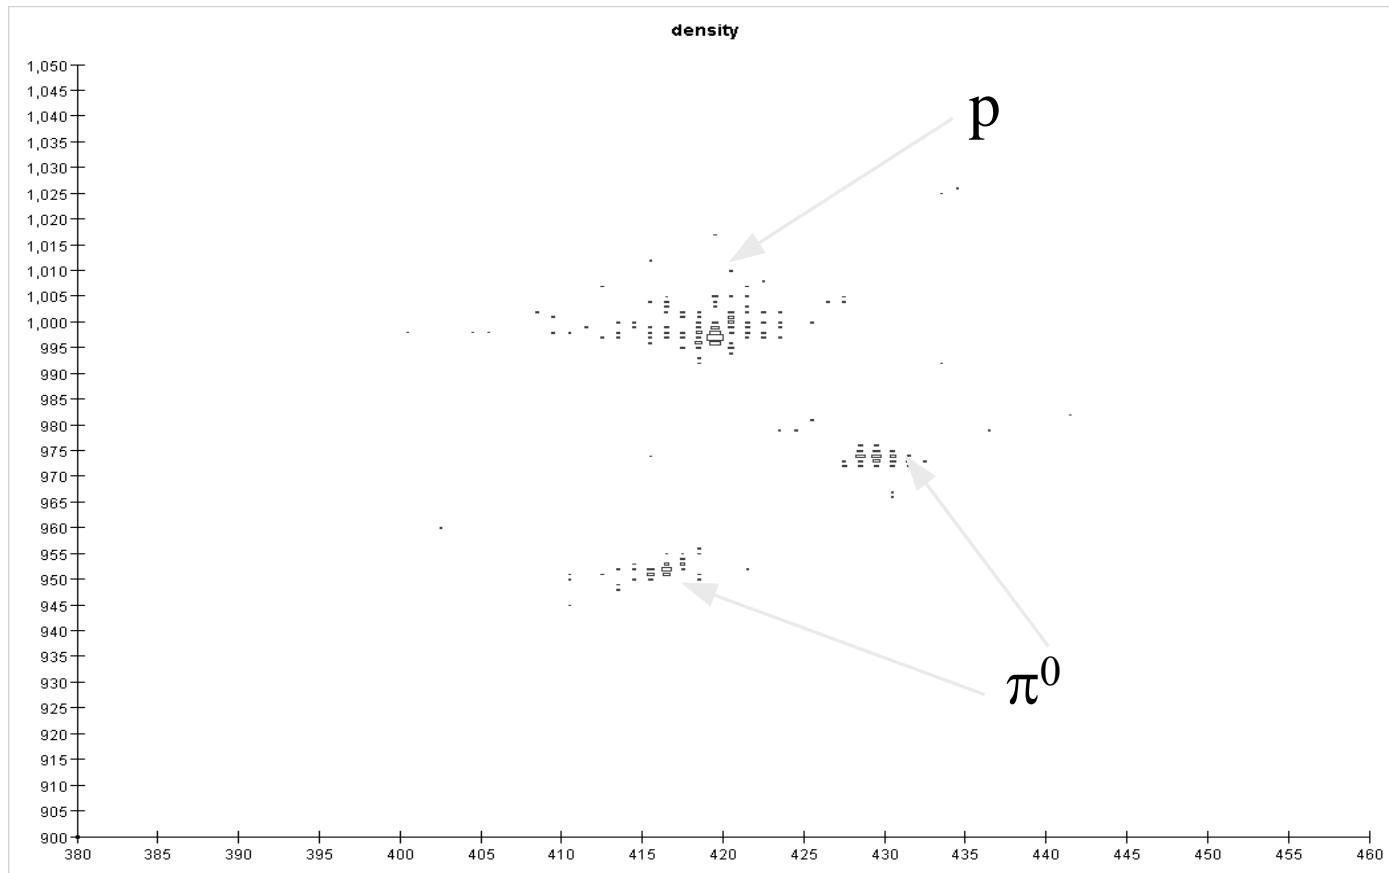

10 GeV $\pi^0 \rightarrow \gamma\gamma$

Density weighted $\theta-\phi$

Density weighted $\theta-\phi$

Summary

- Large parameter space in the nbit-segmentation–medium plane for hadron calorimetry. Optimization through cost-benefit analysis?
- Scintillator and Gas-based ‘digital’ HCals behave differently.
- Need to simulate detector effects (noise, x-talk, non-linearities, etc.)
- Need verification in test-beam data.
- More studies underway.
